ABSTRACT

Background

Accurate rapid diagnostic tests for SARS-CoV-2 infection could contribute to clinical and public health strategies to manage the COVID-19 pandemic. Point-of-care antigen and molecular tests to detect current infection could increase access to testing and early confirmation of cases, and expediate clinical and public health management decisions that may reduce transmission.

Objectives

To assess the diagnostic accuracy of point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection. We consider accuracy separately in symptomatic and asymptomatic population groups.

Search methods

Electronic searches of the Cochrane COVID-19 Study Register and the COVID-19 Living Evidence Database from the University of Bern (which includes daily updates from PubMed and Embase and preprints from medRxiv and bioRxiv) were undertaken on 30 Sept 2020. We checked

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

repositories of COVID-19 publications and included independent evaluations from national reference laboratories, the Foundation for Innovative New Diagnostics and the Diagnostics Global Health website to 16 Nov 2020. We did not apply language restrictions.

Selection criteria

We included studies of people with either suspected SARS-CoV-2 infection, known SARS-CoV-2 infection or known absence of infection, or those who were being screened for infection. We included test accuracy studies of any design that evaluated commercially produced, rapid antigen or molecular tests suitable for a point-of-care setting (minimal equipment, sample preparation, and biosafety requirements, with results within two hours of sample collection). We included all reference standards that define the presence or absence of SARS-CoV-2 (including reverse transcription polymerase chain reaction (RT-PCR) tests and established diagnostic criteria).

Data collection and analysis

Studies were screened independently in duplicate with disagreements resolved by discussion with a third author. Study characteristics were extracted by one author and checked by a second; extraction of study results and assessments of risk of bias and applicability (made using the QUADAS-2 tool) were undertaken independently in duplicate. We present sensitivity and specificity with 95% confidence intervals (CIs) for each test and pooled data using the bivariate model separately for antigen and molecular-based tests. We tabulated results by test manufacturer and compliance with manufacturer instructions for use and according to symptom status.

Main results

Seventy-eight study cohorts were included (described in 64 study reports, including 20 pre-prints), reporting results for 24,087 samples (7,415 with confirmed SARS-CoV-2). Studies were mainly from Europe (n = 39) or North America (n = 20), and evaluated 16 antigen and five molecular assays.

We considered risk of bias to be high in 29 (37%) studies because of participant selection; in 66 (85%) because of weaknesses in the reference standard for absence of infection; and in 29 (37%) for participant flow and timing. Studies of antigen tests were of a higher methodological quality compared to studies of molecular tests, particularly regarding the risk of bias for participant selection and the index test. Characteristics of participants in 35 (45%) studies differed from those in whom the test was intended to be used and the delivery of the index test in 39 (50%) studies differed from the way in which the test was intended to be used. Nearly all studies (97%) defined the presence or absence of SARS-CoV-2 based on a single RT-PCR result, and none included participants meeting case definitions for probable COVID-19.

Antigen tests

Forty-eight studies reported 58 evaluations of antigen tests. Estimates of sensitivity varied considerably between studies. There were differences between symptomatic (72.0%, 95% CI 63.7% to 79.0%; 37 evaluations; 15530 samples, 4410 cases) and asymptomatic participants (58.1%, 95% CI 40.2% to 74.1%; 12 evaluations; 1581 samples, 295 cases). Average sensitivity was higher in the first week after symptom onset (78.3%, 95% CI 71.1% to 84.1%; 26 evaluations; 5769 samples, 2320 cases) than in the second week of symptoms (51.0%, 95% CI 40.8% to 61.0%; 22 evaluations; 935 samples, 692 cases). Sensitivity was high in those with cycle threshold (Ct) values on PCR \leq 25 (94.5%, 95% CI 91.0% to 96.7%; 36 evaluations; 2613 cases) compared to those with Ct values >25 (40.7%, 95% CI 31.8% to 50.3%; 36 evaluations; 2632 cases). Sensitivity varied between brands. Using data from instructions for use (IFU) compliant evaluations in symptomatic participants, summary sensitivities ranged from 34.1% (95% CI 29.7% to 38.8%; Coris Bioconcept) to 88.1% (95% CI 84.2% to 91.1%; SD Biosensor STANDARD Q). Average specificities were high in symptomatic and asymptomatic participants, and for most brands (overall summary specificity 99.6%, 95% CI 99.0% to 99.8%).

At 5% prevalence using data for the most sensitive assays in symptomatic people (SD Biosensor STANDARD Q and Abbott Panbio), positive predictive values (PPVs) of 84% to 90% mean that between 1 in 10 and 1 in 6 positive results will be a false positive, and between 1 in 4 and 1 in 8 cases will be missed. At 0.5% prevalence applying the same tests in asymptomatic people would result in PPVs of 11% to 28% meaning that between 7 in 10 and 9 in 10 positive results will be false positives, and between 1 in 3 cases will be missed.

No studies assessed the accuracy of repeated lateral flow testing or self-testing.

Rapid molecular assays

Thirty studies reported 33 evaluations of five different rapid molecular tests. Sensitivities varied according to test brand. Most of the data relate to the ID NOW and Xpert Xpress assays. Using data from evaluations following the manufacturer's instructions for use, the average sensitivity of ID NOW was 73.0% (95% CI 66.8% to 78.4%) and average specificity 99.7% (95% CI 98.7% to 99.9%; 4 evaluations; 812 samples, 222 cases). For Xpert Xpress, the average sensitivity was 100% (95% CI 88.1% to 100%) and average specificity 97.2% (95% CI 89.4% to 99.3%; 2 evaluations; 100 samples, 29 cases). Insufficient data were available to investigate the effect of symptom status or time after symptom onset.

Authors' conclusions

Antigen tests vary in sensitivity. In people with signs and symptoms of COVID-19, sensitivities are highest in the first week of illness when viral loads are higher. The assays shown to meet appropriate criteria, such as WHO's priority target product profiles for COVID-19 diagnostics ('acceptable' sensitivity \geq 80% and specificity \geq 97%), can be considered as a replacement for laboratory-based RT-PCR when immediate

decisions about patient care must be made, or where RT-PCR cannot be delivered in a timely manner. Positive predictive values suggest that confirmatory testing of those with positive results may be considered in low prevalence settings. Due to the variable sensitivity of antigen tests, people who test negative may still be infected.

Evidence for testing in asymptomatic cohorts was limited. Test accuracy studies cannot adequately assess the ability of antigen tests to differentiate those who are infectious and require isolation from those who pose no risk, as there is no reference standard for infectiousness. A small number of molecular tests showed high accuracy and may be suitable alternatives to RT-PCR. However, further evaluations of the tests in settings as they are intended to be used are required to fully establish performance in practice.

Several important studies in asymptomatic individuals have been reported since the close of our search and will be incorporated at the next update of this review. Comparative studies of antigen tests in their intended use settings and according to test operator (including self-testing) are required.

PLAIN LANGUAGE SUMMARY

How accurate are rapid tests for diagnosing COVID-19?

What are rapid point-of-care tests for COVID-19?

Rapid point-of-care tests aim to confirm or rule out COVID-19 infection in people with or without COVID-19 symptoms. They:

- are portable, so they can be used wherever the patient is (at the point of care);
- are easy to perform, with a minimum amount of extra equipment or complicated preparation steps;
- are less expensive than standard laboratory tests;
- do not require a specialist operator or setting; and
- provide results 'while you wait'.

We were interested in two types of commercially available, rapid point-of-care tests: antigen and molecular tests. Antigen tests identify proteins on the virus; they come in disposable plastic cassettes, similar to pregnancy tests. Rapid molecular tests detect the virus's genetic material in a similar way to laboratory methods, but using smaller devices that are easy to transport or to set up outside of a specialist laboratory. Both test nose or throat samples.

Why is this question important?

People with suspected COVID-19 need to know quickly whether they are infected, so that they can self-isolate, receive treatment, and inform close contacts. Currently, COVID-19 infection is confirmed by a laboratory test called RT-PCR, which uses specialist equipment and often takes at least 24 hours to produce a result.

Rapid point-of-care tests could open access to testing for many more people, with and without symptoms, potentially in locations other than healthcare settings. If they are accurate, faster diagnosis could allow people to take appropriate action more quickly, with the potential to reduce the spread of COVID-19.

What did we want to find out?

We wanted to know whether commercially available, rapid point-of-care antigen and molecular tests are accurate enough to diagnose COVID-19 infection reliably, and to find out if accuracy differs in people with and without symptoms.

What did we do?

We looked for studies that measured the accuracy of any commercially produced, rapid antigen or molecular point-of-care test, in people tested for COVID-19 using RT-PCR. People could be tested in hospital or the community. Studies could test people with or without symptoms.

Tests had to use minimal equipment, be performed safely without risking infection from the sample, and have results available within two hours of the sample being collected.

What we found

We included 64 studies in the review. They investigated a total of 24,087 nose or throat samples; COVID-19 was confirmed in 7415 of these samples. Studies investigated 16 different antigen tests and five different molecular tests. They took place mainly in Europe and North America.

Main results

Antigen tests

In people with confirmed COVID-19, antigen tests correctly identified COVID-19 infection in an average of 72% of people with symptoms, compared to 58% of people without symptoms. Tests were most accurate when used in the first week after symptoms first developed (an average of 78% of confirmed cases had positive antigen tests). This is likely to be because people have the most virus in their system in the first days after they are infected.

In people who did not have COVID-19, antigen tests correctly ruled out infection in 99.5% of people with symptoms and 98.9% of people without symptoms.

Different brands of tests varied in accuracy. Pooled results for one test (SD Biosensor STANDARD Q) met World Health Organization (WHO) standards as 'acceptable' for confirming and ruling out COVID-19 in people with signs and symptoms of COVID-19. Two more tests met the WHO acceptable standards (Abbott Panbio and BIONOTE NowCheck) in at least one study.

Using summary results for SD Biosensor STANDARD Q, if 1000 people with symptoms had the antigen test, and 50 (5%) of them really had COVID-19:

- 53 people would test positive for COVID-19. Of these, 9 people (17%) would not have COVID-19 (false positive result).

- 947 people would test negative for COVID-19. Of these, 6 people (0.6%) would actually have COVID-19 (false negative result).

In people with no symptoms of COVID-19 the number of confirmed cases is expected to be much lower than in people with symptoms. Using summary results for SD Biosensor STANDARD Q in a bigger population of 10,000 people with no symptoms, where 50 (0.5%) of them really had COVID-19:

- 125 people would test positive for COVID-19. Of these, 90 people (72%) would not have COVID-19 (false positive result).

- 9,875 people would test negative for COVID-19. Of these, 15 people (0.2%) would actually have COVID-19 (false negative result).

Molecular tests

Although overall results for diagnosing and ruling out COVID-19 were good (95.1% of infections correctly diagnosed and 99% correctly ruled out), 69% of the studies used the tests in laboratories instead of at the point-of-care and few studies followed test manufacturer instructions. Most of the data relate to the ID NOW and Xpert Xpress tests. We noted a large difference in COVID-19 detection between the two tests, but we cannot be certain about whether results will remain the same in a real world setting. We could not investigate differences in people with or without symptoms, nor time from when symptoms first showed because the studies did not provide enough information about their participants.

How reliable were the results of the studies?

In general, studies that assessed antigen tests used more rigorous methods than those that assessed molecular tests, particularly when selecting participants and performing the tests. Sometimes studies did not perform the test on the people for whom it was intended and did not follow the manufacturers' instructions for using the test. Sometimes the tests were not carried out at the point-of-care. Nearly all the studies (97%) relied on a single negative RT-PCR result as evidence of no COVID-19 infection. Results from different test brands varied, and few studies directly compared one test brand with another. Finally, not all studies gave enough information about their participants for us to judge how long they had had symptoms, or even whether or not they had symptoms.

What does this mean?

Some antigen tests are accurate enough to replace RT-PCR when used in people with symptoms. This would be most useful when quick decisions are needed about patient care, or if RT-PCR is not available. Antigen tests may be most useful to identify outbreaks, or to select people with symptoms for further testing with PCR, allowing self-isolation or contact tracing and reducing the burden on laboratory services. People who receive a negative antigen test result may still be infected.

Several point-of-care molecular tests show very high accuracy and potential for use, but more evidence of their performance when evaluated in real life settings is required.

We need more evidence on rapid testing in people without symptoms, on the accuracy of repeated testing, testing in non-healthcare settings such as schools (including self-testing), and direct comparisons of test brands, with testers following manufacturers' instructions.

How up-to-date is this review?

This review updates our previous review and includes evidence published up to 30 September 2020.

SUMMARY OF FINDINGS

Trusted evidence. Informed decisions. Better health.

Cochrane Database of Systematic Reviews

Summary of findings 1. Diagnostic accuracy of point-of-care antigen and molecular-based tests for the diagnosis of SARS-CoV-2 infection

Cochrane Database of Systematic Reviews

BACKGROUND

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the resulting COVID-19 pandemic present important diagnostic evaluation challenges. These range from: understanding the value of signs and symptoms in predicting possible infection; assessing whether existing biochemical and imaging tests can identify infection or people needing critical care; and evaluating whether in vitro diagnostic tests can accurately identify and rule out current SARS-CoV-2 infection, and identify those with past infection, with or without immunity.

We are creating and maintaining a suite of living systematic reviews to cover the roles of tests and patient characteristics in the diagnosis of COVID-19. This review is the first update of a review summarising evidence of the accuracy of rapid antigen and molecular tests that are suitable for use at the point of care. In some scenarios the tests could potentially be used as alternatives to standard laboratory-based molecular assays, such as reverse transcription polymerase chain reaction (RT-PCR) assays, that are relied on for identifying current infection, in others they may be used where no testing is currently done. If sufficiently accurate, point-of-care tests have the potential to greatly expand access and speed of testing, In turn, if accurate, they may have greater impact on public health than laboratory-based molecular methods as they are less expensive, provide results more quickly and do not require the same technical expertise and laboratory capacity. These tests can be undertaken locally, avoiding the need for centralised testing facilities that rarely meet the needs of patients, caregivers, health workers and society as a whole, especially in low- and middleincome countries. As these are rapid tests, their results can be returned within the same clinical encounter, facilitating timely decisions concerning the need for isolation and contract tracing activities.

Target condition being diagnosed

COVID-19 is the disease caused by infection with the SARS-CoV-2 virus. The key target conditions for this suite of reviews are current SARS-CoV-2 infection, current COVID-19 disease, and past SARS-CoV-2 infection. The tests included in this review concern the identification of current infection, as defined by reference standard methods of diagnosis, including molecular assays such as RT-PCR, or internationally recognised clinical guidelines for diagnosis of SARS-CoV-2. In the context of test evaluation, and throughout this review, we use the term 'reference standard' to denote the best available method (test or tests) for diagnosing the target condition, as opposed to other uses of the term in diagnostic virology (such as reference methods or reference materials).

For current infection, the severity of the disease is of ultimate importance for patient outcomes. However, rapid testing does not establish severity of disease, and for this review we consider the role of point-of-care tests for detecting SARS-CoV-2 infection of any severity, distinguishing only between symptomatic and asymptomatic infection.

COVID-19 public health interventions focus on reducing disease transmission, thus it is important to identify and isolate people who are infected before or whilst they are infectious. It is reasonably presumed that people with symptoms who meet national criteria for COVID-19 testing, or who are identified through contact tracing, have a high enough risk of being infectious to ask them to isolate. However, assessing the risk of an individual being infectious in asymptomatic screening is more difficult, as there is no reference standard test for being 'infectious'. Using RT-PCR status as a reference standard (as is done for target condition of 'infection') will ensure that infectious people are not missed, but as RT-PCR continues to detect viral RNA days and weeks after the onset of infection will wrongly classify some people as infectious. Alternative reference standards that have been proposed for infectiousness include assessing the viability of the virus using viral culture, or using a value of the cycle threshold (Ct value) from RT-PCR results to group individuals above or below a particular value (as a proxy for viral load) as more or less likely to be infectious. Converting Ct values (also known as quantification cycle (Cq) or crossing point (Cp) values) into direct quantitative values of viral load (viral copies per cell) is possible but challenging, as the relationship between Ct values and viral load varies between machines and laboratories. Thus comparison at fixed Ct values is unlikely to be comparable across studies. Viral culture is unsuitable as a reference standard because it is technically complex and often unreliable, which leads to it being an insensitive test (the failure to culture virus potentially being a result of the culture technique and not an indicator of non-infectiousness). The suitability of RT-PCR is limited as the inverse relationship between viral load (Ct value) and risk of infection is a continuum of risk without there being a meaningful cut-point (with virus being cultured from samples with Ct values as high as 35 (Singanayagam 2020)). Similarly, those with low viral loads at the onset of infection will be missed. A preferable alternative, of tracking contacts for evidence of secondary infections, requires longitudinal follow-up and is better considered as a question about risk of transmission, which can be addressed using predictive modelling approaches (taking into account host, agent and environmental factors). This is in contrast to the diagnostic test accuracy paradigm which can only determine if individuals are infected at a single point in time.

For these reasons, this review only focuses on the target condition of 'infection' for both symptomatic and asymptomatic applications of tests. We do report results where they are presented split by an RT-PCR Ct value to report on accuracy according to groups with higher and lower viral load, but advise caution on their interpretation considering the lack of standardisation of PCR Ct values. Given the current state of the scientific knowledge we do not consider it appropriate to consider these as groups which are defined as 'infectious' and 'not infectious'.

RT-PCR carries a very small risk of false positive results for infection and a higher risk of false negative results. False positive results may result from failures in sampling or laboratory protocols (e.g. mislabelling), contamination during sampling or processing, or low-level reactions during PCR (Healy 2020; Mayers 2020). At times when SARS-CoV-2 infections have been rare, population prevalence surveys using RT-PCR have shown test positivity rates of 0.44% (95% credible interval: 0.22% to 0.76%) (August 2020; ONS 2020), and 0.077% (0.065%, 0.092%) (June to July 2020; Riley 2020 React-1 study). These values can be used to place an upper bound on the possible false positive rate of RT-PCR of less than 0.077% (as the total numbers testing positive will comprise both true positive and false positive RT-PCR results). The World Health Organization (WHO) recently issued a notice of concern regarding interpretation of specimens at or near the limit for PCR positivity (i.e. those with high cycle threshold (Ct) values), citing potential difficulties in distinguishing the presence of the target virus from these types of

background 'noise' (WHO 2020a). False negative rates have been estimated by looking at individuals with symptoms who initially test negative, but positive on a subsequent test. These rates have been estimated to be as high as 20% to 30% in the first week of symptom onset; Arevalo-Rodriguez 2020; Yang 2020a; Zhao 2020; Kucirka 2020). Including probable COVID-19 cases within the target condition, as defined by internationally recognised clinical guidelines for diagnosis of SARS-CoV-2 will partially mitigate these missed cases.

Index test(s)

The primary consideration for the eligibility of tests for inclusion in this review is that they should detect current infection and should have the capacity to be performed at the 'point of care' or in a 'nearpatient' testing role. There is an ongoing debate around the specific use and definitions of these terms, therefore for the purposes of this review, we consider 'point-of-care' and 'near patient' to be synonymous, but for consistency and avoidance of confusion, we use the term 'point-of-care' throughout.

We have adapted a definition of point-of-care testing, namely that it "refers to decentralized testing that is performed by a minimally trained healthcare professional near a patient and outside of central laboratory testing" (WHO 2018), with the additional caveat that test results must be available within a single clinical encounter (Pai 2012). Our criteria for defining a point-of-care test are therefore:

- the equipment for running and or reading the assay must be portable or easily transported, although mains power may be required;
- minimal sample preparation requirements, for example, singlestep mixing, with no requirement for additional equipment or precise sample volume transfer unless a disposable automatic fill or graduated transfer device is used;
- minimal biosafety requirements, for example, personal protective equipment (PPE) for sample collector and test operator, good ventilation and a biohazard bag for waste disposal;
- no requirement for a temperature-controlled environment; and
- test results available within two hours of sample collection.

Tests for detection of current infection that are currently suitable for use at the point of care include antigen tests and molecularbased tests. Both types of test use the same respiratory-tract samples acquired by swabbing, washing or aspiration as for laboratory-based RT-PCR. Rapid antigen tests use lateral flow immunoassays, which are disposable devices, usually in the form of plastic cassettes akin to a pregnancy test. Viral antigen is captured by dedicated antibodies that are either colloidal gold- or fluorescent-labelled. Antigen detection is indicated by visible lines appearing on the test strip (colloidal gold-based immunoassays, or CGIA), or through fluorescence, which can be detected using an immunofluorescence analyser (fluorescence immunoassays or FIA). Molecular-based tests to detect viral ribonucleic acid (RNA) have historically been laboratory-based assays using RT-PCR technology (see Alternative test(s)). In recent years, automated, single-step RT-PCR methods have been developed, as well as other nucleic acid amplification methods, such as isothermal amplification, that do not require the sophisticated thermo cycling involved in RT-PCR (Green 2020). These technological advances have allowed molecular technologies to be developed that are

suitable for use in a point-of-care context (Kozel 2017), however they still require small portable machines and many take longer to produce results than antigen tests.

Following the emergence of COVID-19 there has been prolific industry activity to develop accurate tests. The Foundation for Innovative Diagnostics (FIND) and Johns Hopkins Centre for Health Security have maintained online lists of available tests for SARS-CoV-2 (FIND 2020). At the time of writing (5 January 2021), FIND listed 129 rapid antigen tests, 118 of which are described as "commercialised" and 92 have been identified as having regulatory approval. These numbers are a substantial increase on the 48 listed, 32 commercialised and 21 with regulatory approval at the time of our original review (19 July 2020). A total of 142 molecular tests were described as automated, including both laboratory-based assays and assays suitable for use outside of a laboratory setting (i.e. near or at the point of care). Further information from FIND indicates that 53 of the 142 assays were categorised as point-of-care or near point-of-care tests, including 43 with regulatory approval. This classification was based on the information provided to FIND by the test manufacturers and does not necessarily mean that these tests meet the criteria for point-of-care tests that we have specified for this review. The numbers of tests of these types will continue to increase over time.

Given the urgent need to identify the evidence base for tests that are available for purchase, the focus of this first update of the review is on tests that are commercially produced. All commercially produced assays are supplied with a specific product code, product inserts or instructions for use (IFU) sheets that document the intended use of the test; sample storage and preparation and testing procedures; who should deliver the test and in whom; and any restrictions around the type of samples that can be used.

There are many proposals for serial testing with lateral flow tests to detect infection, rather than a single use. In this case it would be appropriate to evaluate the accuracy of the strategy rather than a single test.

Clinical pathway

Patients may be tested for SARS-CoV-2 when they present with symptoms, have had known exposure to a confirmed case, or in a screening context, with no known exposure to SARS-CoV-2. The standard approach to diagnosis of SARS-CoV-2 infection is through laboratory-based testing of swab samples taken from the upper respiratory (e.g. nasopharynx, oropharynx) or lower respiratory tract (e.g. bronchoalveolar lavage or sputum) with RT-PCR. RT-PCR is the primary method for detecting infection during the acute phase of the illness while the virus is still present. Both the WHO and the China CDC (National Health Commission of the People's Republic of China), have produced case definitions for COVID-19 that include the presence of convincing clinical evidence (some including positive serology tests) when RT-PCR is negative (Appendix 1).

Prior test(s)

Signs and symptoms are used in the initial diagnosis of suspected SARS-CoV-2 infection and to help identify those requiring tests. A number of key symptoms have been suggested as indicators of mild to moderate COVID-19, including: cough, fever greater than 37.8 °C, headache, breathlessness, muscle pain, fatigue, and loss of sense of smell and taste (Struyf 2021). However, the recently

published review of signs and symptoms found good evidence for the accuracy for these symptoms alone or in combination to be lacking (Struyf 2021).

Where people are asymptomatic but are being tested as part of screening (e.g. universal testing of students as part of a riskreduction effort) or on the basis of epidemiological risk factors, such as exposure to someone with confirmed SARS-CoV-2 or following travel to more highly endemic countries, no prior tests will have been conducted.

Role of index test(s)

For most settings in which testing for acute SARS-CoV-2 infection in symptomatic individuals takes place, results of molecular laboratory-based RT-PCR tests are unlikely to be available within a single clinical encounter. Point-of-care tests potentially have a role either as a replacement for RT-PCR (if sufficiently accurate), or as a means of triaging and rapid management (quarantine or treatment, or both), with confirmatory RT-PCR testing for those with negative rapid test results (CDC 2020; WHO 2020b). Obtaining quick results within a healthcare visit will allow faster decisions about isolation and healthcare interventions for those with positive test results, and allow contact tracing to begin in a more timely manner. Modelling studies suggest contact tracing is most effective if it starts within 24 hours of case detection, with delays in testing (e.g. due to laboratory turnaround time for reporting PCR results) leading to reductions in the proportion of onward transmissions per index case that can be prevented by track and trace (Kretzschmar 2020).

If sufficiently accurate, negative rapid test results in symptomatic patients could allow faster return to work or school, therefore conferring important economic and educational implications. Negative results also allow immediate consideration of other causes of symptoms, which may be time-sensitive, for example bacterial pneumonia or thrombo-embolism.

For asymptomatic individuals, if accurate, rapid tests may also be considered for screening at-risk (exposed) populations, for example in hospital workers or in local outbreaks.

Rapid tests, particularly antigen tests which can be more easily delivered at scale, could also be used for mass screening purposes as recently piloted in Slovakia and in Liverpool UK (University of Liverpool 2020), or used in a more targeted fashion such as single test application at airports or for border entry, to allow entry to large public gatherings, or screening students as a risk-reduction strategy (Ferguson 2020). Preliminary data on the rollout of such a policy in the UK has highlighted the many challenges in such an approach (Deeks 2020a; Nabavi 2021), and the requirement for full and proper field trial evaluations. Frequent repeated use of antigen tests in asymptomatic individuals with no known exposure to identify COVID-19 cases has also been proposed (Larremore 2020), but field trial evaluations would be required to determine whether promising results from modelling studies can be borne out in practical settings (Crozier 2021).

Alternative test(s)

This review is one of seven that cover the range of tests and clinical characteristics being considered in the management of COVID-19 (Deeks 2020b; McInnes 2020), five of which have already been published (Deeks 2020c; Salameh 2020; Stegeman 2020; Struyf 2021), including the first iteration of this review (Dinnes 2020). Full

details of the alternative tests and evidence of their accuracy is summarised in these reviews. The SARS-CoV-2-specific biomarker tests that might be considered as alternatives to point-of-care tests are considered here.

Laboratory-based molecular tests

RT-PCR tests for SARS-CoV-2 identify viral ribonucleic acid (RNA). Reagents for RT-PCR were rapidly produced once the viral RNA sequence was published (Corman 2020). Testing is undertaken in central laboratories and can be very labour-intensive, with several points along the path of performing a single test where errors may occur, although some automation of parts of the process is possible. The amplification process requires thermal cycling equipment to allow multiple temperature changes within a cycle, with cycles repeated up to 40 times until viral DNA is detected (Carter 2020). Although the amplification process for RT-PCR can be completed in a relatively short timeframe, the stages of extraction, sample processing and data management (including reporting) mean that test results are typically only available in 24 to 48 hours. Where testing is undertaken in a centralised laboratory, transport times increase this further. The time to result for fully automated RT-PCR assays is shorter than for manual RT-PCR, however most assays still require sample preparation steps that make them unsuitable for use at the point of care. Other nucleic acid amplification methods, including loop-mediated isothermal amplification (LAMP), or CRISPR-based nucleic acid detection methods, that allow amplification at a constant temperature are now commercially available (Chen 2020). These methods have the potential to reduce the time to produce test results after extraction and sample processing to minutes, but the time for the whole process may still be significant. Laboratory-based molecular tests are most often applied to upper and lower respiratory samples although they are also being used on faecal and urine samples.

Antibody tests

Serology tests to measure antibodies to SARS-CoV-2 have been evaluated in people with active infection and in convalescent cases (Deeks 2020c). Antibodies are formed by the body's immune system in response to infections, and can be detected in whole blood, plasma or serum. Antibody tests are available for laboratory use including enzyme-linked immunosorbent assay (ELISA) methods, or more advanced chemiluminescence immunoassays (CLIA). There are also rapid lateral flow assays (LFA)s for antibody testing that use a minimal amount of whole blood, plasma or serum on a testing strip as opposed to the respiratory specimens that are used for rapid antigen tests; all assays for antibody detection are considered in Deeks 2020c.

Rationale

It is essential to understand the clinical accuracy of tests and clinical features to identify the best way they can be used in different settings to develop effective diagnostic and management pathways for SARS-CoV-2 infection and disease. The suite of Cochrane living systematic reviews summarises evidence on the clinical accuracy of different tests and diagnostic features. Estimates of accuracy from these reviews will help inform diagnosis, screening, isolation, and patient-management decisions.

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

Summary of the previous version of the review

The first iteration of this review (Dinnes 2020), included 22 publications reporting on a total of 18 study cohorts with 3198 unique samples, 1775 of which had confirmed SARS-CoV-2 infection. We identified data for eight commercial tests (four antigen and four molecular) and one in-house antigen test.

We did not find any studies at low risk of bias and had concerns about applicability of results across all studies. We judged patient selection to be at high risk of bias in 50% of the studies because of deliberate oversampling of samples with confirmed SARS-CoV-2 infection (sample enrichment) and unclear in 38% (7/18) because of poor reporting. Sixteen (89%) studies used only a single, negative RT-PCR to confirm the absence of SARS-CoV-2 infection, risking missing infection. There was a lack of information on blinding of index test (n = 11), and about participant exclusions from analyses (n = 10). We did not observe differences in methodological quality between antigen and molecular test evaluations.

The eight evaluations of antigen tests reported considerable variation in sensitivity across studies (from 0% to 94%) with less variation in specificities (from 90% to 100%). The average sensitivity was 56.2% (95% CI 29.5 to 79.8%) and average specificity was 99.5% (95% CI 98.1% to 99.9%) (based on 943 samples, 596 with confirmed SARS-CoV-2). Data for individual antigen tests were limited with no more than two studies for any test.

We observed less variation in sensitivities across 13 evaluations of rapid molecular assays (range 68% to 100%) with similar variation in specificities (range 92% to 100%). Average sensitivity was 95.2% (95% CI 86.7% to 98.3%) and specificity 98.9% (95% CI 97.3% to 99.5%) based on a total of 2255 samples.

We were able to calculate pooled results for only two molecular tests: ID NOW (Abbott Laboratories; 5 evaluations) and Xpert Xpress (Cepheid Inc; 6 evaluations). Summary sensitivity for the Xpert Xpress assay (99.4%, 95% CI 98.0% to 99.8%) was 22.6 (95% CI 18.8 to 26.3) percentage points higher than that of ID NOW (76.8%, (95% CI 72.9% to 80.3%), whilst the specificity of Xpert Xpress (96.8%, 95% CI 90.6% to 99.0%) was marginally lower than ID NOW (99.6%, 95% CI 98.4% to 99.9%; a difference of -2.8 percentage points (95% CI from 6.4 percentage points lower to 0.8 higher).

Changes in the evidence base since the previous version

There has been a considerable increase in the number of evaluations available of antigen tests, and a lesser rise in the number of evaluations of molecular tests. More studies report key population features such as setting, and symptom status, and there has been an increase in direct swab testing as would occur in a point-of-care setting. However, due to the nature of sampling and the use of direct swab testing, few comparative studies are available. This review considers the available evidence in relevant population groups and settings according to test brand and compliance with manufacturer IFUs. We used the WHO's priority target product profiles for COVID-19 diagnostics (i.e. acceptable performance criterion of sensitivity $\ge 80\%$ and specificity $\ge 97\%$, or desirable criterion of $\ge 80\%$ sensitivity and $\ge 99\%$ specificity; WHO 2020c) as a benchmark against which to consider test performance.

We will update this review as often as is feasible to ensure that it provides current evidence about the accuracy of point-of-care tests.

This review follows a generic protocol that covers six of the seven Cochrane COVID-19 diagnostic test accuracy reviews (Deeks 2020b). The Background and Methods sections of this review therefore use some text that was originally published in the protocol (Deeks 2020b), and text that overlaps some of our other reviews (Deeks 2020c; Struyf 2021).

OBJECTIVES

To assess the diagnostic accuracy of rapid point-of-care antigen and molecular-based tests to determine if a person presenting in the community or in primary or secondary care has current SARS-CoV-2 infection, and to consider accuracy separately in symptomatic and asymptomatic population groups.

We estimated accuracy overall and separately according to symptom status (symptomatic and asymptomatic). Although we might expect to see differences in accuracy for testing of asymptomatic individuals with an epidemiological exposure to SARS-CoV-2 (targeted screening) compared to testing of asymptomatic individuals in a population screening setting, we did not anticipate finding sufficient numbers of studies for each testing application to allow any such difference to be explored. We will revisit this decision in subsequent iterations of this review.

Secondary objectives

Where data are available, we will investigate potential sources of heterogeneity that may influence diagnostic accuracy (either by stratified analysis or meta-regression) according to test method and index test, participant or sample characteristics (duration of symptoms and viral load), study setting, study design and reference standard used.

We investigated adherence to manufacturers' IFUs in sensitivity analyses.

METHODS

Criteria for considering studies for this review

Types of studies

We applied broad eligibility criteria to include all patient groups (that is, if patient population was unclear, we included the study) and all variations of a test.

We included studies of all designs that produce estimates of test accuracy or provide data from which we can compute estimates, including the following.

- Studies restricted to participants confirmed to either have (or to have had) the target condition (to estimate sensitivity) or confirmed not to have (or have had) the target condition (to estimate specificity). These types of studies may be excluded in future review updates.
- Single-group studies, which recruit participants before disease status has been ascertained
- Multi-group studies, where people with and without the target condition are recruited separately (often referred to as two-gate or diagnostic case-control studies)
- · Studies based on either patients or samples

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

We excluded studies from which we could not extract data to compute either sensitivity or specificity.

We carefully considered the limitations of different study designs in the quality assessment and analyses.

We included studies reported in published journal papers, as preprints, and publicly available reports from independent bodies.

Participants

We included studies recruiting people presenting with suspicion of current SARS-CoV-2 infection or those recruiting populations where tests were used to screen for disease (for example, contact tracing or community screening).

We also included studies that recruited people known to have SARS-CoV-2 infection and known not to have SARS-CoV-2 infection (i.e. cases only or multi-group studies).

We excluded small studies with fewer than 10 samples or participants. Although the size threshold of 10 is arbitrary, such small studies are likely to give unreliable estimates of sensitivity or specificity and may be biased.

Index tests

We included studies evaluating any rapid antigen or molecularbased test for diagnosis of SARS-CoV-2, if it met the criteria outlined in the Background, that is:

- requiring minimal equipment;
- minimal sample preparation and biosafety considerations;
- results available within two hours of sample collection; and
- should be commercially produced (with test name and manufacturer or distributor documented).

All sample types (respiratory or non-respiratory) were eligible. Strategies based on multiple applications of a test were also eligible for inclusion.

Target conditions

The target condition was current SARS-CoV-2 infection (either symptomatic or asymptomatic). We also refer to SARS-CoV-2 infection as 'COVID-19 infection', particularly in the Plain Language Summary and Summary of findings 1.

Reference standards

We anticipated that studies would use a range of reference standards to define both the presence and absence of SARS-CoV-2 infection. For the QUADAS-2 (Quality Assessment tool for Diagnostic Accuracy Studies; Whiting 2011), assessment we categorised each method of defining the presence of SARS-CoV-2 according to the risk of bias (the chances that it would misclassify the presence or absence of infection) and whether it defined COVID-19 in an appropriate way that reflected cases encountered in practice. Likewise, we considered the risk of bias in definitions of the absence of SARS-CoV-2, and whether the definition captured all those who might be tested in practice.

Evaluations of molecular tests generally consider agreement between molecular assays, for example, agreement of a new rapid test against a more standard RT-PCR test. For the purposes of this review, we considered RT-PCR to be the 'reference standard' for SARS-CoV-2 infection, and present results as 'sensitivity' and 'specificity' as opposed to percentage agreement. The result of further RT-PCR analysis of discrepant cells (samples with results disagreeing on the rapid test and the RT-PCR) were also considered in sensitivity analyses. As discrepant analysis involves retesting only a sub-sample of patients selected according to index and reference standard results, it can introduce bias (Hadgu 1999). Retesting of all samples with a second test in a composite reference standard would be preferable when there are concerns over the accuracy of the first reference test.

Search methods for identification of studies

Electronic searches

We used two main sources for our electronic searches through 30 September 2020, which were devised with the help of an experienced Cochrane Information Specialist with diagnostic test accuracy review expertise (RSp). These searches aimed to identify all articles related to COVID-19 and SARS-CoV-2 and were not restricted to those evaluating a particular type of test. Thus, the searches used no terms that specifically focused on an index test, diagnostic accuracy or study methodology.

Cochrane COVID-19 Study Register searches

We used the Cochrane COVID-19 Study Register (covid-19.cochrane.org/), for searches conducted from inception of the Register to 28 March 2020. At that time, the register was populated by searches of PubMed, as well as trials registers at US National Institutes of Health Ongoing Trials Register ClinicalTrials.gov (clinicaltrials.gov) and the WHO International Clinical Trials Registry Platform (apps.who.int/trialsearch).

Search strategies were designed for maximum sensitivity, to retrieve all human studies on COVID-19 and with no language limits. See Appendix 2.

COVID-19 Living Evidence Database from the University of Bern

From 28 March 2020, we used the COVID-19 Living Evidence database from the Institute of Social and Preventive Medicine (ISPM) at the University of Bern (www.ispm.unibe.ch), as the primary source of records for the Cochrane COVID-19 diagnostic test accuracy reviews. This search includes PubMed, Embase, and preprints indexed in bioRxiv and medRxiv databases. The strategies as described on the ISPM website are described here (ispmbern.github.io/covid-19/). See Appendix 3. To ensure comprehensive coverage we also downloaded records from the 'Bern feed' from 1 January to 28 March 2020 and de-duplicated them against those obtained via the Cochrane COVID-19 Study Register.

Due to the increased volume of published and preprint articles, from 25 May 2020 onwards we used artificial intelligence text analysis to conduct an initial classification of documents, based on their title and abstract information, for relevant and irrelevant documents (Appendix 4).

The decision to focus primarily on the Bern feed was because of the exceptionally large numbers of COVID-19 studies available only as preprints. We are continuing to monitor the coverage of the Cochrane COVID-19 Study Register and may move back to it as the primary source of records for subsequent review updates.

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

Other electronic sources

ochrane

Prior to 28 March 2020 (when we began using the 'Bern feed'), we identified Embase records through the Centers for Disease Control and Prevention (CDC), Stephen B Thacker CDC Library, COVID-19 Research Articles Downloadable Database (cdc.gov/library/ researchguides/2019novelcoronavirus/researcharticles.html), and de-duplicated them against results from the Cochrane COVID-19 Study Register. See Appendix 5.

We also checked our search results against two additional repositories of COVID-19 publications up to 30 September 2020:

- the Evidence for Policy and Practice Information and Coordinating Centre (EPPI-Centre) 'COVID-19: Living map of the evidence' (eppi.ioe.ac.uk/COVID19_MAP/covid_map_v4.html);
- the Norwegian Institute of Public Health 'NIPH systematic and living map on COVID-19 evidence' (www.nornesk.no/ forskningskart/NIPH_diagnosisMap.html)

Both repositories allow their contents to be filtered according to studies potentially relating to diagnosis, and both have agreed to provide us with updates of new diagnosis studies added.

Searching other resources

We have also contacted or accessed the websites of independent research groups undertaking test evaluations (for example, UK Public Health England (PHE), the Société Française Microbiologie (SFM), the Dutch National Institute for Public Health and the Environment (RIVM)) and studies co-ordinated by FIND (finddx.org/covid-19/sarscov2-eval) and accessed the Diagnostics Global Health listing of manufacturer independent evaluations of antigen detecting rapid diagnostic tests (Ag-RDTs) for SARS-CoV-2 (diagnosticsglobalhealth.org). We last accessed these additional resources on 16 November 2020.

We appeal to researchers to supply details of additional published or unpublished studies at the following email address, which we will consider for inclusion in future updates (coviddta@contacts.bham.ac.uk).

Data collection and analysis

Selection of studies

A team of experienced systematic review authors from the University of Birmingham screened the titles and abstracts of all records retrieved from the literature searches following the application of artificial intelligence text analysis (described in Electronic searches). Two review authors independently screened studies in Covidence. A third, senior review author resolved any disagreements. We tagged all records selected as potentially eligible according to the Cochrane COVID-19 diagnostic test accuracy review(s) for which they might be eligible and we then exported them to separate Covidence reviews for each review title.

We obtained the full texts for all studies flagged as potentially eligible. Two review authors independently screened the full texts for one of the COVID-19 biomarker reviews (molecular, antigen or antibody tests). We resolved any disagreements on study inclusion through discussion with a third review author.

Data extraction and management

One review author extracted the characteristics of each study, which a second review author checked. Items that we extracted are listed in Appendix 6.

Both review authors independently performed data extraction of 2x2 contingency tables of the number of true positives, false positives, false negatives and true negatives. They resolved disagreements by discussion. Where possible, we separately extracted data according to symptom status (symptomatic, asymptomatic, mixed symptom status or not reported), viral load (high or low, according to Ct cut-offs defined within each study), and time post-symptom onset (week one versus week two) and for molecular assays, before and after re-analysis of samples in discrepant cells. For categorisation by symptom status, we classed studies reporting at least 75% of participants as symptomatic as 'mainly symptomatic', we considered studies with less than 75% symptomatic participants to report 'mixed' groups along with those that reported recruiting both symptomatic and asymptomatic participants but did not provide the percentages in each group. We considered studies that provided no information as to the symptom status of included participants 'not reported'. We also coded evaluations according to compliance with manufacturer IFUs. We based coding on three aspects of testing:

- 1. sample type (use of any sample not explicitly mentioned on the IFU scored 'No', otherwise scored 'Yes'),
- provision of instructions for samples in viral transport medium ((VTM); only scored for evaluations using samples in VTM and only scored 'Yes' if specific instructions provided; scored 'Unclear' if VTM used and instructions for use of samples in VTM not documented in IFU); and
- 3. timing between sample collection and testing (scored 'Yes' only if all tests were carried out within specified time period, e.g. immediate on-site testing, or for testing in laboratories if all tests reported to have been carried out within specified time period; scored 'Unclear' if time frame for testing was not reported and 'No' if any testing was carried out beyond the maximum stipulated timeframe).

We encourage study authors to contact us regarding missing details on the included studies (coviddta@contacts.bham.ac.uk).

Assessment of methodological quality

Two review authors independently assessed risk of bias and applicability concerns using the QUADAS-2 checklist tailored to this review (Appendix 7; Whiting 2011). The two review authors resolved any disagreements by discussion.

Ideally, studies examining the use of tests in symptomatic people should prospectively recruit a representative sample of participants presenting with signs and symptoms of COVID-19, either in community or primary care settings or to a hospital setting, and they should clearly record the time of testing after the onset of symptoms. Studies in asymptomatic people at risk of infection should document time from exposure. Studies applying tests in a screening setting should document eligibility criteria for screening, particularly if a targeted approach is used and should take care to record any previous confirmed or suspected SARS-CoV-2 infection or any relevant epidemiological exposures. Studies should perform tests in their intended use setting, using appropriate samples with

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

or without viral transport medium and within the time period following specimen collection as indicated in the IFU document. Tests should be performed by relevant personnel (e.g. healthcare workers), and should be interpreted blinded to the final diagnosis (presence or absence of SARS-CoV-2). The reference standard diagnosis should be blinded to the result of the rapid test, and should not incorporate the result of the rapid test. If the reference standard includes clinical diagnosis of COVID-19 for RT-PCR-negative patients, then established criteria should be used. Studies including samples from participants known not to have COVID-19 should use pre-pandemic sources or if contemporaneous samples then at least two RT-PCR-negative tests were required to confirm the absence of infection. Data should be reported for all study participants, including those where the result of the rapid test was inconclusive, or participants in whom the final diagnosis of COVID-19 was uncertain. Studies should report whether results relate to participants (one sample per participant), or samples (multiple samples per participant).

Statistical analysis and data synthesis

We analysed rapid antigen and molecular tests separately. Studies often referred to 'samples' rather than 'patients', especially for the rapid molecular tests, however for many studies we do not suspect that inclusion of multiple samples per study participant was a significant issue. For consistency of terminology throughout the review, we refer to results on a per-sample basis. If studies evaluated multiple tests in the same samples, we included them multiple times. We present estimates of sensitivity and specificity per study for each test brand using paired forest plots, and summarise results using average sensitivity and specificity in tables as appropriate. As heterogeneity is apparent in many analyses, these point estimates must be interpreted as the average of a distribution of values.

We did not make any formal comparisons between antigen assay brands because of the large number of different assays and small study numbers for many of them. We did however carry out a formal comparison (based on between-study comparisons) for studies using two brands of molecular tests (ID NOW (Abbott Laboratories) and Xpert Xpress (Cepheid Inc)).

We estimated summary sensitivities and specificities with 95% confidence intervals (CI) using the bivariate model (Reitsma 2005), via the meqrlogit command of Stata/SE 16.0. When few studies were available, we simplified models by first assuming no correlation between sensitivity and specificity estimates and secondly by setting near-zero variance estimates of the random effects to zero (Takwoingi 2017). In cases where there was only one study per test, we reported individual sensitivities and specificities with 95% CI constructed using the binomial exact method.

Where studies presented only estimates of sensitivity or of specificity, we fitted univariate, random-effects, logistic regression models. In a number of instances where there was 100% sensitivity or specificity for all evaluations, we computed estimates and 95% CIs by summing the counts of TP, FP, FN and TN across 2x2 tables. These analyses are clearly marked in the tables. We present all estimates with 95% confidence intervals.

Investigations of heterogeneity

We examined heterogeneity between studies by visually inspecting the forest plots of sensitivity and specificity. Where adequate data were available, we investigated heterogeneity related to symptom status, time post-symptom onset, viral load, test brand, and test method by including indicator variables in the randomeffects logistic regression models. Absolute differences between the sensitivity or specificity and the P values were reported from the model. In instances where only one study was available per test or when tests were being directly compared following summing of counts of the 2x2 tables, we performed test comparison using the two-sample test of proportions. Few studies reported specificity estimates by time after symptom onset, therefore for this variable and for analyses by viral load, we considered only effects on sensitivity.

Sensitivity analyses

We performed four sensitivity analyses.

- 1. We estimated summary sensitivities and specificities according to test brand and symptom status using only studies that were compliant to the IFU.
- 2. We estimated sensitivity with and without studies that only evaluated samples with RT-PCR-confirmed SARS-CoV-2 (and thus did not estimate specificity).
- 3. We performed the same analysis for specificity in studies that only evaluated RT-PCR-negative control samples.
- 4. We made comparisons between analyses using the primary reference standard and analyses using results adjusted after retesting of samples with discrepant results with a second RT-PCR test (discrepant analysis).

Assessment of reporting bias

We made no formal assessment of reporting bias but have indicated where we were aware that study results were available but unpublished.

Summary of findings

We summarised key findings in a 'Summary of findings' table indicating the strength of evidence for each test and findings, and highlighted important gaps in the evidence.

Updating

We are aware of additional studies published since the electronic searches were conducted on 30 September 2020 and plan to update this review. We have already conducted the next search to 1 January 2021.

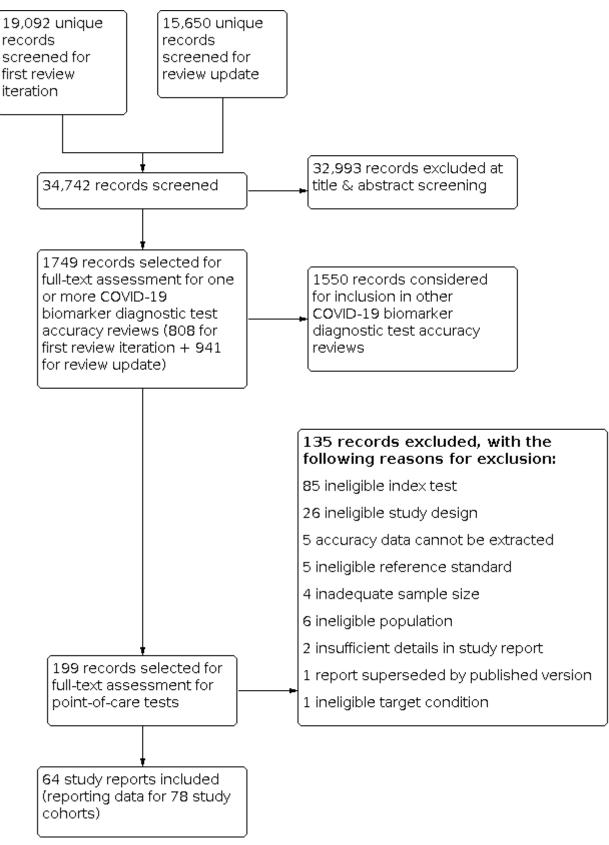

RESULTS

Results of the search

We screened 34,742 unique records (published or preprints) for inclusion in the complete suite of reviews to assist in the diagnosis of COVID-19 (Deeks 2020b; McInnes 2020). Of 1749 records selected for further assessment for inclusion in any of the four molecular, antigen or antibody test reviews, we identified 199 full-text reports requiring assessment for inclusion in this review; 90 for the first iteration of the review and 109 for this review update. See Figure 1 for the PRISMA flow diagram of search and eligibility results (McInnes 2018; Moher 2009).

Figure 1. Study flow diagram

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

We included 64 reports in this review, and we excluded 135 publications that did not meet our inclusion criteria. Exclusions were mainly based on index test (n = 85) or ineligible study designs (n = 26), for example, designs that did not allow estimation of test accuracy. The reasons for exclusion of all 135 publications are provided in Characteristics of excluded studies. Appendix 8 provides a list of studies evaluating eligible tests but excluded for other reasons (n = 5), and studies evaluating technologies not yet suitable for use at the point of care (n = 41).

Of the 64 study reports, 18 were available only as preprints, 38 were published papers and eight were publicly available reports either from independent reference laboratories (one from Public Health England and two identified via the SMF) or were independent evaluations co-ordinated by FIND (n = 5).

We contacted the authors of 10 study reports for further information (Blairon 2020; Courtellemont 2020; Diao 2020; Gibani 2020; Gremmels 2020(a); Linares 2020; Nash 2020; Porte 2020a; Schildgen 2020 [A]; Weitzel 2020 [A]), and received replies and the requested information with one exception (Linares 2020). We also contacted the evaluation teams at FIND and Public Health England and received additional information about study methods from FIND and some additional data from Public Health England.

The 64 included study reports relate to 78 separate studies. Please note when naming studies, we use the letters [A], [B], [C] etc. in square brackets to indicate data on different tests evaluated in the same study and (a), (b), (c) to indicate data from different participant cohorts from the same study report. For example, the five included reports from FIND correspond to eight 'studies' because three reports separately provided data from more than one evaluation centre.

Of the 78 studies, 77 reported data for respiratory samples and one (Szymczak 2020), reported data for faecal samples. The main results, Tables and Figures focus on the respiratory samples, with Szymczak 2020 reported separately.

Description of included studies

The 77 studies using respiratory samples included a total of 24,418 unique samples, with 7484 samples with RT-PCR-confirmed SARS-CoV-2 (some samples were analysed by more than one index test). Forty-eight studies evaluated antigen tests (Albert 2020; Alemany 2020; Billaud 2020; Blairon 2020; Cerutti 2020; Courtellemont 2020; Diao 2020; Fenollar 2020(a); Fenollar 2020(b); FIND 2020a; FIND 2020b; FIND 2020c (BR); FIND 2020c (CH); FIND 2020d (BR); FIND 2020d (DE); FIND 2020e (BR); FIND 2020e (DE); Fourati 2020 [A]; Gremmels 2020(a); Gremmels 2020(b); Gupta 2020; Kruger 2020(a); Kruger 2020(b); Kruger 2020(c); Lambert-Niclot 2020; Linares 2020; Liotti 2020; Mak 2020; Mertens 2020; Nagura-Ikeda 2020; Nash 2020; PHE 2020(a); PHE 2020(b); PHE 2020(c) [non-HCW tested]; PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]; PHE 2020(e); Porte 2020a; Porte 2020b [A]; Schildgen 2020 [A]; Scohy 2020; Shrestha 2020; Takeda 2020; Van der Moeren 2020(a); Van der Moeren 2020(b); Veyrenche 2020; Weitzel 2020 [A]; Young 2020) and 29 studies evaluated molecular tests (Assennato 2020; Broder 2020; Chen 2020a; Collier 2020; Cradic 2020(a); Cradic 2020(b); Dust 2020; Ghofrani 2020; Gibani 2020; Goldenberger 2020; Harrington 2020; Hogan 2020; Hou 2020; Jin 2020; Jokela 2020; Lephart 2020 [A]; Lieberman 2020; Loeffelholz 2020; Mitchell 2020; Moore 2020; Moran 2020; Rhoads 2020; Smithgall 2020 [A]; SoRelle 2020; Stevens 2020; Thwe 2020; Wolters 2020; Wong 2020; Zhen 2020 [A]). Summary study characteristics are presented in Table 1 with further details of study design and index test details in Appendix 9 and Appendix 10 for antigen assays and Appendix 11 and Appendix 12 for molecular assays. Full details are provided in the Characteristics of included studies table.

The median sample size of the included studies is 182 (interquartile range (IQR) 104 to 400) and median number of SARS-CoV-2 confirmed samples included is 63 (IQR 38 to 119). Sample sizes for antigen test evaluations were larger than those for molecular test evaluations (median 291.5 (IQR 155 to 502.5) compared to 104 (IQR 75 to 172)). Half of the studies (39/77, 51%) were conducted in Europe, 20 in North America, seven in South America, seven in Asia, one study included samples from more than one country and in one, the country of sample origin was unclear.

Participant characteristics

Antigen tests

Over half of the antigen test studies included samples from participants presenting in the community for COVID-19 testing at: community test centres (22/48, 46%); emergency departments (3, 6%); or as part of contact tracing or outbreak investigations (4, 8%) (Table 1). Eleven antigen test studies (23%) selected samples from those submitted to laboratories for routine RT-PCR testing with limited detail of the participants providing the samples ('laboratory-based' studies), or included multiple (8%) or unclear (2%) settings. Over half of antigen test studies were conducted in symptomatic (16, 33%) or mainly symptomatic (11, 23%) populations, with only three (6%) exclusively in asymptomatic populations (two in asymptomatic contacts of confirmed cases (Fenollar 2020(b); Shrestha 2020), and one involved staff screening, all of whom were RT-PCR-negative (PHE 2020(e)). The remaining antigen studies included samples from populations with mixed symptom status (8, 17%) or provided no information regarding symptom status (10, 21%). Of the 10 that provided no information, seven were laboratory-based studies providing no details of the settings from which the tested samples had been obtained, one included samples from a COVID-19 test centre, one was an outbreak investigation and in one the study setting could not be derived. There were no studies evaluating strategies of multiple tests.

A total of 13 studies provided accuracy data for people with no symptoms at the time of testing (3 studies exclusively in asymptomatic populations, and 10 studies providing subgroup data for people with no reported symptoms); one study provided only specificity data. Of the 12 datasets reporting both sensitivity and specificity, one (Alemany 2020), purportedly described preventive screening of the general population (although the reported prevalence of 24% is very high for such a scenario), one (Cerutti 2020), described targeted traveller screening, four (Billaud 2020; Fenollar 2020(b); Gupta 2020; Shrestha 2020), tested contacts of confirmed cases (one as part of an outbreak investigation) and the remaining six datasets were subgroups of samples from people presenting for routine testing. We identified one additional asymptomatic dataset in a report of several substudies but we did not include it as participants underwent antigen testing up to five days after a positive PCR test and it was not possible to determine the time point at which symptom status was recorded; it was also not possible to determine which 'substudy' the data related to (PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]).

Thirty-one of the 48 studies evaluating antigen tests reported results for SARS-CoV-2-confirmed samples above and below a Ct value from the reference standard RT-PCR. The median proportion of participants with 'high' viral load was 52% (IQR 35% to 60%). The most commonly used threshold was 24 or 25 Ct or less (n = 29 studies (or 36/58 test evaluations); 11 studies (15/58 test evaluations) reported results with at a threshold of between 31 and 33 Ct or less ; and 13 studies (13 evaluations) reported other thresholds including less than: 28 Ct (n = 3), 30 Ct (n = 5), 31 Ct (n = 3), or 35 Ct (n = 2)

Molecular tests

In contrast, studies evaluating molecular tests were mainly laboratory-based (20, 69%), with three (10%) including samples from participants presenting to emergency department or urgent care settings, two in hospital inpatients (7%), and four (14%) including samples from participants presenting in multiple settings. Twelve of the 29 studies (41%) reported included only samples from symptomatic patients, four reported mixed symptom status (10%) and 14 (48%) provided no information regarding symptom status. Of the 14 that provided no information, one was based in a hospital Accident and Emergency department, and the remaining 13 were laboratory-based studies, only three of which gave any details of the settings from which the tested samples had been obtained (three reported inclusion of samples from either inpatients and outpatients (n = 1), inpatients and ambulatory patients (n = 1) or inpatients and emergency department patients (n = 1) but did not provide the number of samples from each source). There were no studies evaluating strategies of multiple tests.

Five studies evaluating molecular assays, reported proportions with high viral load ranging from 33% to 80%, median 46%. All five studies reported results above and below a Ct value of 30.

Study design and reference standards

Table 1 shows a similar distribution of study designs between those evaluating antigen and molecular tests. Overall, 60% of studies (n = 46) used a 'single group' design to estimate both sensitivity and specificity and 22% (n = 17) used a 'two group' design with separate selection of RT-PCR-positive and RT-PCR-negative samples. In four studies (5%), the design could not be fully determined but probably deliberate separate sampling of RT-PCR-positive and RT-PCR-positive and RT-PCR-negative samples had been used.

Nine studies included only samples with confirmed SARS-CoV-2, thus only allowing estimation of sensitivity (six antigen and three molecular assay studies), and one study included only SARS-CoV-2-negative samples allowing estimation of specificity only. All studies defined the presence or absence of SARS-CoV-2 infection based on RT-PCR. Of the 68 studies that included SARS-CoV-2-negative samples, 63 (93%) required a single, negative PCR to confirm absence of infection and two (3%) required two negative PCR results. The remaining three studies used pre-pandemic samples (n = 2) or contemporaneous samples with other respiratory infections.

Thirty-three studies (43%), obtained paired swabs for index and reference standard, 39 (51%) used the same swab for point-of-care and RT-PCR (18 antigen and 21 molecular studies) and five studies used a mix of paired and same swabs (n = 1) or it was not possible to determine this information from the study report.

Index tests

Fifteen studies evaluated only one test, seven compared two or more tests in the same participants (four with two tests each, one with three tests and one each with four or five tests). In total the 77 studies that used respiratory samples reported on a total of 90 test evaluations. Appendix 13 provides details extracted from the manufacturer's instructions for use documents for all included tests.

Antigen tests

Forty-eight studies reported 58 evaluations of antigen tests; 41 of CGIAs, nine FIA, two alternative type of LFA using alkaline phosphatase-labelled antibodies, and six where assay type could not be determined. Studies evaluated 16 different commercially produced assays, as documented, with full assay identification details, in Appendix 13. One study reported the development of the Shenzhen Bioeasy assay (Diao 2020), but it is not clear whether the commercially available assay is identical to the one reported in the study or whether it has undergone further refinement. One study reported evaluating a Roche SARS-CoV-2 assay, which appears to be the SD Biosensor STANDARD Q (Schildgen 2020 [A]). Only 12 studies provided product codes for the tests evaluated (FIND 2020a; FIND 2020b; FIND 2020c (BR); FIND 2020c (CH); FIND 2020d (BR); FIND 2020d (DE); FIND 2020e (BR); FIND 2020e (DE); Gremmels 2020(a); Gremmels 2020(b); Porte 2020a; Weitzel 2020 [A]). The study reports or manufacturer IFUs for 11 assays reported targeting the nucleocapsid protein; this information was not reported for the Beijing Savant, Bionote, Biosynex, Liming Bio-Products, or RapiGEN Inc assays (Appendix 13). We were unable to identify any information for Beijing Savant, E25Bio or Liming Bio-Products assays online.

Multiple combinations of sample types and use of direct swab testing or swabs in viral transport medium or saline were reported across the studies (Table 1). Forty-one of 58 evaluations used nasopharyngeal (n = 30), oropharyngeal (n = 1) or nasal (n = 2) samples (type of nasal sample was not reported), or combinations of nasopharyngeal, nasal or oropharyngeal samples (n = 8; nasopharyngeal or nasal mid-turbinate in one, nasopharyngeal or combined naso- and oropharyngeal in two, naso- or oropharyngeal in two, and naso- or oropharyngeal or combined naso- and oropharyngeal samples in three. Thirteen evaluations used combined naso- and oropharyngeal samples for all participants, one used saliva samples and three evaluations (from one study) used bronchoalveolar lavage or throat wash samples. Of the six studies using nasal samples either alone (n = 2) or for at least some participants (n = 4), one reported that these were nares swabs, and the remaining five did not specify the type of nasal sample. Almost half of studies used direct swab testing (n = 28, 48%), 22 (38%) tested samples in viral transport medium, saline or other medium, and in 8 (14%) this information was not provided.

IFUs for five assays explicitly recommend against using any transport medium for swab testing (assays from Becton Dickinson, Bionote, Quidel and SD Biosensor; Appendix 13), one (Coris BioConcept) states that viral transport medium may be used, and the other nine do not mention use of transport medium, although two of the nine (from AAZ and Biosynex) imply that viral transport medium should not be used (using statements such as "use within one hour, stored in clean unused plastic tube"). We considered 29 of 58 antigen evaluations (50%) to be compliant with manufacturer

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

IFUs in terms of sample type, use of viral transport medium and time interval between collection and testing. Sixteen evaluations were not compliant with IFUs; nine used viral transport medium, four used freezing, four tested samples not listed on the IFUs, and in two testing was not always conducted within the one-hour time period specified in the IFU. For the remaining 13 evaluations either no IFU was available (n = 4), viral transport medium or saline was used but the IFU did not specifically address whether viral transport medium was recommended or not (n = 7), or insufficient detail was provided in the study.

Samples were collected by healthcare workers in 15 (26%) evaluations, by trained non-healthcare workers, such as firefighters or Ministry of Health employees in three (5%) evaluations, self-collected in six (10%) and the collection was not described in 34 evaluations (59%). Sample testing was conducted 'on-site' immediately or within one hour of collection in 21 (36%) evaluations by the same healthcare workers (n = 13), trained non-healthcare workers (n = 3) who collected the samples, or this information was not provided (n = 5). In the remaining 27 evaluations (47%), testing was conducted by laboratory staff (n = 12) or was inferred to be by laboratory staff (n = 15). For the latter group, the time interval between sample collection and testing was on receipt at the laboratory, some reporting delays of up to six hours.

Molecular tests

Twenty-nine studies reported 32 evaluations of five different commercially available rapid molecular tests: 13 evaluating ID NOW (Abbott Laboratories), 15 evaluating Xpert Xpress (Cepheid Inc), two of SAMBA II (Diagnostics for the Real World), and one evaluation each of Accula (Mesa Biotech Inc.) and COVID Nudge (DNANudge). None of the studies reported product codes for the tests evaluated. One study of Xpert Xpress used the 'research use only' (RUO) version of the test but reported that the RUO version contains the same reagents as the 'emergency use authorisation' (EUA) version. The RUO test allows the user to view the amplification curves for the RdRp gene as well as for the E-gene and N2 targets whereas the EUA version restricts the amplification curves to E and N2 only. ID NOW and SAMBA-II use isothermal techniques, Xpert Xpress and COVID Nudge are based on RT-PCR, and Accula is described as a PCR plus lateral flow assay.

Multiple combinations of sample types and use of direct swab testing or swabs in viral transport medium or saline were reported across the studies (Table 1). The sample types used included combined naso- and oropharyngeal samples (n = 2), nasopharyngeal samples alone (n = 16), nasal alone (n = 2), oropharyngeal samples alone (n = 1), or a combination of two or more of either nasopharyngeal or nasal or oropharyngeal samples (n = 8). One evaluation used throat saliva or lower respiratory tract specimens, one used saliva samples alone and one did not specify the sample type used. Of the six studies using nasal samples either alone (n = 2) or for at least some participants (n = 4), one reported using nares swabs, and the remaining five did not specify the type of nasal sample used.

Eight evaluations (25%) reported direct swab testing in some (n = 1) or all (n = 7) samples, 18 (59%) used swabs in viral transport medium only (n = 12) or in viral transport medium or some other transport medium (n = 6), and six did not report whether they used any transport medium.

Sample collection was described in only three evaluations (9%) (Gibani 2020; Harrington 2020; Rhoads 2020; Table 1); the remaining studies did not describe sample collection but it is likely that samples were collected as part of routine care by healthcare workers. Sample testing was clearly described as conducted onsite by medical personnel or by laboratory personnel at local laboratories in one of the studies reporting sample collection (Harrington 2020), while a second implied testing as soon as possible after collection, possibly by the same healthcare worker (Gibani 2020). Four (12.5%) evaluations stated that laboratory staff carried out the tests. In 16 of the remaining 26 studies, testing by laboratory staff was inferred, based on delays between collection and testing of 18 hours to seven days (n = 10), or reported use of archived or frozen samples (n = 6). The remaining eight evaluations provided no useful information regarding who carried out the test (Assennato 2020; Dust 2020; Ghofrani 2020; Jin 2020; Jokela 2020; Moran 2020; Rhoads 2020; SoRelle 2020).

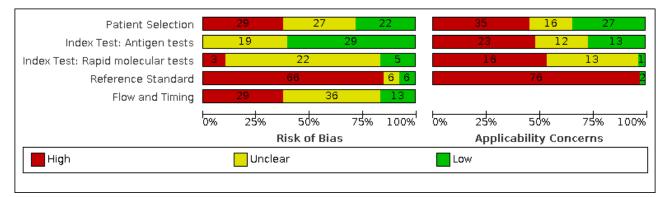

Two of the five manufacturers document IFU for samples stored in transport medium (Xpert Xpress and SAMBA II assays); two explicitly recommend against the use of viral transport medium (ID NOW and Accula), although at the time of the test evaluations some viral transport media were documented as acceptable for ID NOW; and one IFU does not mention the use of viral transport medium (COVID Nudge). Although immediate sample testing is preferred, all manufacturers document an acceptable period of refrigerated storage of between eight hours (COVID Nudge), and seven days with refrigeration (Xpert Xpress). See Appendix 13.

We considered only nine of 32 (28%) evaluations to be compliant with manufacturer IFUs in regard to sample type, use of viral transport medium and time interval between collection and testing. Sixteen evaluations were not compliant with IFUs; eight used viral transport medium, six used frozen samples, and two tested samples not listed on the IFUs. For the remaining seven evaluations, either the testing interval from sample collection was unclear (n = 5) or saline was used but the IFU did not specifically address whether this was recommended or not (n = 2).

Methodological quality of included studies

We report the overall methodological quality assessed using the QUADAS-2 tool for all included studies (n = 78) in Figure 2 (Whiting 2011). See Appendix 14 for separate summary plots by test method and for a plot of study-level ratings by quality domain. We explain how we reached these judgements in the Characteristics of included studies table.

Figure 2. Risk of bias and applicability concerns graph: review authors' judgements about each domain presented as percentages across included studies. Numbers in the bars indicate the number of studies

We considered whether the findings of individual studies were at risk of bias, and whether there were concerns that results might not apply to standard use of the tests. We did not judge any study at low risk of bias, although in 11 of 78 studies the only concern was that a single negative RT-PCR was used to confirm absence of COVID infection rather than the preferred two negative tests. All studies raised concerns regarding the applicability of their results, but in 13 of 78 studies the only concern was the reliance on only PCR to identify SARS-COV-2 cases (and nine of these 13 are in common with the 11 using a single negative RT-PCR).

Participant selection

We judged 22 studies (28%) to be at low risk of bias, and 29 (37%) at high risk of bias because of deliberate sampling of participants based on the reference standard result (n = 25; 16 two-group studies and nine that only included samples with confirmed SARS-CoV-2 infection or absence of infection) or use of convenience sampling (n = 4). In 27 studies (35%) the risk of bias was unclear because of poor reporting of recruitment procedures or inclusion criteria (Figure 2).

A third (27/78) of studies were likely to have selected an appropriate patient group, recruiting participants from COVID-19 test centres, urgent care or emergency departments or identified through contact tracing. We had high concerns about the applicability of the selected participants in almost half of studies (35/78). Recruited participants were unlikely to be similar to those in whom the test would be used in clinical practice because of deliberate sampling (n = 25) or sample inclusion based on the availability of residual and sometimes frozen samples, or both (n = 22).

Index tests

Poor reporting meant we could not clearly assess whether there was a risk of bias through performance of the index test in 41 (53%) studies. In general, antigen test studies were of a higher methodological standard for the index test domain compared to studies of molecular tests (Figure 2).

For antigen tests, we observed low risk of bias in 60% of studies (29/48). Risk of bias was unclear in the remaining studies because we could not judge whether interpretation of the index test was undertaken with knowledge of the reference standard result. For molecular tests, risk of bias was low in only 17% of studies (5/30). We observed high risk of bias in three studies (Moran 2020; Smithgall 2020 [A]; Wolters 2020) because they did not follow the manufacturer's prespecified threshold for the Xpert Xpress test (re-

testing of samples with presumptive positive results). Risk of bias was unclear in 73% (22/30) of studies because they did not report blinding to the reference standard (n = 22), six of these studies also did not report how they handled presumptive positive results on Xpert Xpress.

Fourteen studies (18%), including 13 antigen and one molecular test study, conducted testing as would be expected in practice (low concern regarding applicability). We had high concerns about applicability in half of all studies (39/78); 48% (23/48) of antigen and 57% (16/30) of molecular studies. Twenty-seven (11 antigen and 16 molecular) did not comply with manufacturers' IFU and a further 10 (all antigen studies), did not carry out tests as would occur in practice (i.e. trained, centralised laboratory staff carried out testing). In another two antigen studies concerns for applicability were high because tests were not available for purchase (Diao 2020; Nash 2020). Of the remaining 25 studies (12 antigen and 13 molecular) 16 conducted the test within the manufacturer IFU but none clearly described the setting for testing or personnel conducting the test.

Reference standards

Six studies were at low risk of bias for the reference standard. Although 12 used an appropriate reference standard, half (6/12) did not clearly implement blinding of the reference standard to the index test. High risk of bias (66/78) was present because studies did not use an adequate reference standard (Figure 2); they used either a single negative RT-PCR to define absence of SARS-CoV-2 infection (n = 64) or the index test formed part of a composite reference standard (n = 2).

A total of 36 studies reported blinded RT-PCR interpretation, two (with composite reference standard) did not implement blinding, and 40 (51%) provided insufficient information about blinding of the reference standard to the index test to judge risk of bias.

We judged 76 of the 78 studies to raise concerns about applicability (97%) because of defining the presence of SARS-CoV-2 infection based on a single RT-PCR-positive result. These studies will have excluded individuals who are RT-PCR-negative but have exposure and clinical features that meet the case definitions for COVID-19.

Flow and timing

Only 13 (17%) studies (all of antigen tests) were at low risk of bias for participant flow and timing (Figure 2). Twenty-nine (37%)

were at high risk of bias (19 antigen and 10 molecular) because of exclusion of samples following invalid index test results (n = 23); delays between 'paired' swabs of up to three days (n = 4), different reference standards used (n = 3), or because they provided results on a per sample instead of per patient basis (n = 2). These categories are not mutually exclusive.

We judged risk of bias unclear for 36 (46%) studies, primarily because of lack of clarity about participant inclusion and exclusion from analyses (n = 34), with no missing data or indeterminate test results reported and no Standards for Reporting Diagnostic Accuracy Studies (STARD)-style participant flow diagram and checklist (Bossuyt 2015), to fully report outcomes for all samples.

Conflicts of interest

In 27 studies all authors declared no conflicts of interest, although one study that reported the validation of a new test included a co-author affiliated to the test manufacturing company. Of these 27 studies, 19 were independent evaluations published by FIND or were from national reference laboratories. Twenty studies did not provide a conflict of interest statement, including 13 published studies and one study that reported affiliations to the test manufacturer. In the 12 remaining studies at least one author declared potential conflicts of interest in relation to the test.

Twenty-six studies provided no funding statement, 12 reported no funding sources to declare, and the remainder (n = 40) reported one or more funding sources.

Findings

Of the 78 included studies, eight reported evaluations of more than one test using the same samples and one reported evaluations of three tests using different samples (Table 1). To include all results from all tests in these analyses we have treated results from different tests of the same samples within a study as separate data points, such that data are available on 91 test evaluations (58 evaluations of antigen tests in 48 studies and 33 evaluations of rapid molecular tests in 30 studies).

As previously stated, 77 of the 78 studies reported data for respiratory samples and one (Szymczak 2020), reported data for non-respiratory (faecal) samples. The main results, Tables and Figures focus on the respiratory samples, with Szymczak 2020 reported separately.

The results tables identify where estimates are based on multiple assessments of the same samples by including both the number of test evaluations and the number of studies. Nine datasets are from 'cases only' studies reporting only sensitivity estimates (six for antigen tests and three for molecular assays), and one antigen test evaluation is for 'non-COVID-19' cases reporting only specificity. Summary results are presented for studies providing both sensitivity and specificity data and then adding in the data from sensitivity- or specificity-only evaluations. The numbers of true positives, false positives, and total samples with and without confirmed SARS-CoV-2 infection are based on test result counts.

We present results for antigen tests overall and by subgroup in Table 2. Table 3 and Table 4 present results by test brand overall and by symptom status, and give results of sensitivity analyses restricting by compliance with manufacturer IFU. Forest plots of study data for the primary analysis are in Figure 3 and for subgroup analyses by symptom status and time after symptom onset are in Figure 4 and Figure 5. Appendix 15 provides forest plots for study data according to Ct value and study design. Individual plots by test brand are provided in Figure 6 for test brands with three or more evaluations and Figure 7 for test brands with one or two evaluations. Figure 8 shows data from studies comparing the accuracy of two or more antigen assays. Full identification details for studies of antigenbased assays are provided in Appendix 9 and Appendix 10.

Results for molecular tests overall and by subgroup are reported in Table 5. Forest plots of study data for the primary analysis is in Figure 9 and for subgroup analyses by Ct value, study design and sensitivity analyses by pre- and post-discrepant analysis in Appendix 16. Individual plots by test brand are provided in Figure 10. Full identification details for studies of molecular-based assays are provided in Appendix 11 and Appendix 12. Appendix 17 provides

forest plots for study data according to Ct value and discrepant analysis.

Accuracy of antigen tests overall and by subgroup

Hogan 2020 34 0 16 50

Results showed high levels of heterogeneity in sensitivity. Average sensitivity was 68.9% (95% CI 61.8% to 75.1%) and average specificity was 99.6% (95% CI 99.0% to 99.8%) across the 51 evaluations of antigen tests reporting both sensitivity and specificity (based on 21,614 samples, including 6136 samples with confirmed SARS-CoV-2; Table 2; Figure 3). Adding the six 'sensitivity only' datasets and single 'specificity only' datasets had a negligible impact on results (Table 2). In the sections below we show that there are substantial differences between subgroups of studies according to symptom status, timing, test method and brand, therefore this average value is unlikely to accurately predict the performance of the test in a given setting and should not be used for this purpose.

No

0.68 [0.53, 0.80]

Subgroup analysis by symptom status

1.00 [0.93, 1.00]

Subgroup analysis by symptom status suggests that average test sensitivity to detect infection is 13.8 percentage points lower in asymptomatic (58.1%, 95% CI 40.2% to 74.1%; based on 12 evaluations, 1581 samples and 295 cases) compared to symptomatic (72.0%, 95% CI 63.7% to 79.0%; based on 37 evaluations, 15,530 samples and 4410 cases) participants (95% CI for the difference in sensitivity: 33.1 percentage points lower to 5.4 percentage points higher; Table 2; Figure 4). Restricting the comparison by symptom status to the nine evaluations reporting data for both symptomatic and asymptomatic subgroups (thus ensuring the comparison is made between the same tests used in the same way) showed a similar difference in sensitivity (14.4 percentage points lower in asymptomatic participants, 95% CI 38.8 lower to 10.0 percentage points higher; Table 2). Average results for the 19 evaluations in participants with mixed symptom status

We did not observe any important differences in specificity according to symptom status (Table 2).

Subgroup analysis by time from symptom onset

We pooled data by time from symptom onset separately for sensitivity and specificity because the majority of evaluations did not report these data for people without SARS-CoV-2 (Table 2; Figure 5). Sensitivity was 78.3% (95% CI 71.1% to 84.1%) (26 evaluations; 5769 samples, 2320 cases) in the first seven days after symptom onset compared to 51.0% (40.8% to 61.0%) (22 evaluations; 935 samples, 692 cases) in the second week of symptoms (a decrease of 27.3 percentage points, 95% CI -32.8 to -21.9 percentage points decrease). This difference remained on restriction to the 22 evaluations reporting data for people in both week one and week two of symptoms (removing other betweenstudy differences; Table 2).

We did not observe any differences in specificity according to time after symptom onset (Table 2).

Subgroup analysis by Ct value

A total of 36 evaluations reported sensitivity according to Ct value using a threshold of 24 (n = 18) or 25 (n = 18) Ct or less to define higher viral load (Table 2; Appendix 15). Summary sensitivity in those with higher viral load was 94.5% (95% Cl 91.0% to 96.7%) (based on 2613 cases), compared to 40.7% in those with lower viral load (95% Cl 31.8% to 50.3%) (based on 2632 cases) (i.e. sensitivity was 53.8 percentage points lower for those with lower viral load; 95% Cl 63.6 to 44.1 percentage points lower)). Applying a Ct threshold of \leq 33 (n = 13) or < 32 (n = 2) led to a bigger difference in sensitivity although the number of samples in the lower viral load subgroup was considerably smaller: sensitivity associated with higher viral load was 82.5% (95% Cl 74.0% to 88.6%) (based on 2127 samples) and for lower viral load was 8.9% (3.3% to 21.7%) (based on 346 samples), a difference of 73.5 percentage points (95% Cl 84.7 to 62.4 percentage points lower).

Subgroup analysis by study design

We did not observe any clear differences in average sensitivity or specificity when studies were grouped by study design (15,336 samples and 3536 cases in 29 single group studies and 5729 samples and 2396 cases in 20 two-group studies; Table 2; Appendix 15). Average sensitivity was lower in two-group studies (64.1%, 95% CI 48.5% to 77.2%) compared to single-group studies (72.1%, 95% CI 64.8% to 78.3%), however confidence intervals overlapped and the difference was within that which may be expected by chance (8.0 percentage points lower, 95% CI from 24.2 percentage points lower to 8.2 higher). Average specificities were 2.3 percentage points lower in the two-group studies (95% CI from 2.9 to 1.6 percentage points lower), at 97.3% (95% CI 96.7% to 97.8%) compared to 99.6% (95% CI 99.1% to 99.8%) in single-group studies.

Subgroup analysis by test method

We observed differences in accuracy according to test method (Table 2). The majority of evaluations (n = 36; 17,448 samples,

5085 cases) reported using a CGIA, average sensitivity was lower (64.0%, 95% CI 55.7% to 71.6%) than for FIAs (79.6%, 95% CI 67.5% to 88.0%; n = 9; 2820 samples, 712 cases; absolute difference of 15.6 percentage points, 95% CI 2.6 to 28.5 percentage points). We also observed marginal differences in specificity, with estimates of 99.0% (95% CI 98.8% to 99.2%) for CGIA and 97.7% (95% CI 95.3% to 98.8%) for FIA, a difference of 1.3 percentage points (95% from 3.0 percentage points lower to 0.3 higher). Results for lateral flow assays where the method could not be determined (n = 5) and for the single evaluation of an alkaline phosphatase (ALP)-labelled assay were heterogeneous but largely in the realms of those observed for the other assay types (Table 2).

Results by test brand according to symptom status and IFU compliance

Results by test brand overall and sensitivity analyses by IFU compliance (based on sample type, use of viral transport medium, and time period between sample collection and test procedure) are reported in Table 3. Results by test brand for symptomatic and asymptomatic subgroups overall and by IFU compliance are in Table 4. Given the mixed settings in which asymptomatic individuals were tested (Results of the search), the data for asymptomatic subgroups cannot be considered applicable to any particular scenario for asymptomatic testing. Only three studies reported direct comparisons of tests, two using nasopharyngeal or oropharyngeal samples (Fourati 2020 [A]; Weitzel 2020 [A]).

We observed considerable heterogeneity in sensitivities for all assays.

AAZ - COVID-VIRO

Two evaluations of the COVID-VIRO assay included 880 samples and 396 SARS-CoV2-positive samples (Figure 7). We did not pool the studies due to the heterogeneity in both sensitivity and specificity, although both were conducted in symptomatic or mainly symptomatic participants using nasopharyngeal samples.

In one study that compared antigen assays using nasopharyngeal samples in viral transport medium, sensitivity was 61.7% (95% CI 55.9% to 67.3%) and specificity (in pre-pandemic samples) 100% (95% CI 98.9% to 100%; 632 samples, 295 cases; 'Fourati 2020 [E]).

The second study used direct swab testing in compliance with the manufacturer's IFU. Twenty participants in the study who previously tested positive on PCR retested negative with PCR at the time of the antigen test. All twenty samples showed weak lines on antigen testing. We considered these as false positives in the review (based on the negative result of the concurrent PCR test) whereas the study authors considered them to be true positives. With our re-calculation, the test demonstrated sensitivity of 96.0% (95% CI 90.2% to 98.9%) and specificity of 86.4% (95% CI 79.8% to 91.5%; Courtellemont 2020). Sensitivity in this study may have been inflated by the inclusion of hospitalised, confirmed SARS-CoV-2positive participants.

Abbott - Panbio Covid-19 Ag

We identified 11 evaluations of the Panbio assay, including 5691 unique samples, with 2031 SARS-CoV-2-positive cases (Figure 6). One of the 11 evaluations included only SARS-CoV-2-positive cases (n = 182 samples). Studies were conducted in community COVID-19 test centres or emergency departments (n = 6), in contacts of confirmed cases (n = 2), and laboratory-based evaluations (n = 2).

The setting was not clear in one study. Participants were reportedly symptomatic (n = 5), asymptomatic (n = 1), with mixed symptom status (n = 4), or symptom status was not reported (n = 1). Nine evaluations used nasopharyngeal samples (Albert 2020; Billaud 2020; Fenollar 2020(b); FIND 2020b; Fourati 2020 [C]; Gremmels 2020(a); Gremmels 2020(b); Linares 2020), one (Alemany 2020), tested nasopharyngeal or nasal samples and one (Schildgen 2020 [A]), used bronchoalveolar lavage or throat wash samples. Only three of the 11 evaluations reported product codes for the assays used, one of which was for the assay for use with nasopharyngeal swabs (41FK10) and two (from the same study report) were for the assay for use with nasal swabs (41FK11), although the study reports using nasopharyngeal samples (Gremmels 2020(a); Gremmels 2020(b)).

Five of the 11 evaluations complied with manufacturer IFU for the test. Reasons for non-compliance included use of viral transport medium, frozen storage, type of swab tested, or lack of clear reporting of test procedures used.

The average sensitivity and specificity of the Panbio assay were:

- 72.0% (95% CI 60.6% to 81.1%) and 99.3% (95% CI 99.0% to 99.6%) overall (n = 10; 5509 samples; 1849 cases; Table 3);
- 74.1% (95% CI 60.8% to 84.0%) and 99.8% (95% CI 99.5% to 99.9%) in symptomatic people (n = 8; 3699 samples, 1162 cases); and
- 58.1% (95% CI 41.7% to 72.9%) and 98.4% (95% CI 92.2% to 99.7%) in asymptomatic people (n = 6; 1097 samples, 190 cases; Table 4).

Restricting to IFU-compliant evaluations, average sensitivities and specificities were:

- 72.0% (95% CI 56.5% to 83.5%) and 99.2% (95% CI 98.5% to 99.5%) overall (n = 5; 1776 samples, 362 cases; Table 3);
- 75.1% (95% CI 57.3% to 87.1%) and 99.5% (95% CI 98.7% to 99.8%) in symptomatic people (n = 3; 1094 samples, 252 cases); and
- 48.9% (95% CI 35.1% to 62.9%) and 98.1% (95% CI 96.3% to 99.1%) in asymptomatic people (n = 2; 474 samples, 47 cases; Table 4).

The addition of one evaluation that reported sensitivity only in symptomatic participants led to only marginal differences in average sensitivity (Fenollar 2020(a); Table 4).

Becton Dickinson - BD Veritor

We identified three evaluations of the BD Veritor assay, including 727 unique samples, with 180 SARS-CoV-2-positive cases (Figure 6). One of the three evaluations included only SARS-CoV-2-positive cases (n = 125 samples). Studies were conducted in community COVID-19 test centres (n = 2), or in multiple settings (n = 1). All participants were symptomatic. Two evaluations used combined naso- and oropharyngeal samples and one tested nasal samples.

None of the evaluations complied with manufacturer IFU for the test because the interval between sample collection and testing was greater than the maximum of one hour.

Average sensitivity and specificity of the BD Veritor assay were:

 82.3% (95% CI 62.1% to 93.0%) and 99.5% (95% CI 98.3%, 99.8%) in symptomatic people (n = 2; 602 samples, 55 cases; Van der Moeren 2020(a); Young 2020; Table 3; Table 4).

Adding the 'cases only' evaluation reduced average sensitivity to 79.4% (95% CI 72.9% to 84.7%) (n = 3; 180 cases; Van der Moeren 2020(b)).

The BD Veritor assay requires interpretation using a Veritor analyzer device, but Van der Moeren 2020(a) found that visual inspection of the test device resulted in the same sensitivity as with the Analyzer device, and similar specificity (100% compared to 99% using the Analyzer device).

BIONOTE - NowCheck COVID-19 Ag

We identified a single IFU-compliant evaluation of the NowCheck assay in symptomatic participants (FIND 2020a; Figure 7). The study included 400 samples with 102 SARS-CoV-2-positive cases, from participants presenting at a community-based COVID-19 test centre.

The sensitivity and specificity in this study were 89.2% (95% CI 81.5% to 94.5%) and 97.3% (95% CI 94.8% to 98.8%; Table 3; Table 4).

Biosynex - Biosynex COVID-19 Ag BSS

We identified a single evaluation of the Biosynex assay in symptomatic participants (Fourati 2020 [D]), including 634 samples with 297 with confirmed SARS-CoV-2 (Figure 7). The evaluation was not in compliance with the manufacturer's IFU because samples were stored in viral transport medium and frozen prior to testing. The setting in which participants presented for testing was not reported.

Observed sensitivity was 59.6% (95% CI 53.8% to 65.2%) and specificity 100% (95% CI 98.9% to 100%; Table 3; Table 4).

Coris Bioconcept - COVID-19 Ag Respi-Strip

The seven evaluations of the Coris Bioconcept assay included 1781 samples, with 707 SARS-CoV-2-positive cases (Blairon 2020; Fourati 2020 [A]; Kruger 2020(b); Lambert-Niclot 2020; Mertens 2020; Scohy 2020; Veyrenche 2020; Figure 6). Five of the seven were laboratory-based evaluations with limited detail regarding study participants. One study recruited from community-based COVID-19 test centres and one included samples from hospital inpatients. Three studies included only or mainly symptomatic participants, one was in a mixed group and three did not report symptom status.

All evaluations tested naso- or oropharyngeal swabs and were compliant with the manufacturer IFU, however, it may be worth noting that the IFU for this assay permits the use of viral transport medium and freezing of samples, although immediate testing is recommended.

The average sensitivity and specificity of the COVID-19 Ag Respi-Strip were:

- 39.7% (95% CI 31.3% to 48.7%) and 98.3% (95% CI 97.4% to 98.9%) overall (n = 7; 1781 samples, 707 cases; Table 3);
- 34.1% (95% CI 29.7% to 38.8%) and 100% (95% CI 99.0% to 100%) in symptomatic people (n = 3; 780 samples, 414 cases); and

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

28.6% (95% CI 8.4% to 58.1%) and 100% (95% CI 88.8% to 100%) in asymptomatic people (n = 1; 45 samples, 14 cases; Scohy 2020; Table 4).

E25Bio - DART (nasopharyngeal)

Cochrane

We identified a single evaluation of the E25Bio DART assay that included 190 samples, 100 with SARS-CoV-2 (Nash 2020; Figure 7). The symptom status of included participants was not reported and the manufacturer IFU is not yet available as the assay has been submitted for Emergency Use Authorisation (EUA) approval with the US Food and Drug Administration (FDA).

Sensitivity was 80.0% (95% CI 70.8% to 87.3%) and specificity 91.1% (95% CI 83.2% to 96.1%; Table 3).

Fujirebio - ESPLINE SARS-CoV-2

We included two eligible evaluations were included, with a total of 265 samples, 165 were SARS-COV-2-positive (Nagura-Ikeda 2020; Takeda 2020; Figure 7). One study reported only sensitivity data (Nagura-Ikeda 2020).

Takeda 2020 reported sensitivity of 80.6% (95% CI 68.6% to 89.6%) and specificity of 100% (95% CI 96.4% to 100%) in nasopharyngeal samples (162 samples, 62 cases; Table 3). They did not report symptom status of participants and provided insufficient detail to allow us to judge IFU compliance.

Nagura-Ikeda 2020 evaluated the assay using saliva samples in symptomatic participants (not within IFU specifications), the ESPLINE assay correctly identified 12 of 103 PCR-positive samples (sensitivity 11.6%, 95% CI 6.2% to 19.5%; Table 3; Table 4).

Innova Medical Group - Innova SARS-CoV-2 Ag

We included one report that evaluated the Innova study as six separate substudies; three reported both sensitivity and specificity (PHE 2020(a); PHE 2020(b); PHE 2020(c) [non-HCW tested]), two reported sensitivity alone (PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]), and one reported specificity alone (PHE 2020(e); Figure 6). The studies reported a total of 3904 participants, including 1017 SARS-CoV-2-positive cases. Detail regarding symptom status, was limited, however the study populations were coded as: symptomatic (samples from hospital inpatients in PHE 2020(a)), mainly symptomatic for samples from COVID-19 testing centres (PHE 2020(c) [non-HCW tested]; PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]), although data on symptom status were reported for only two of these studies (PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]), not reported for the outbreak investigation in PHE 2020(b) and asymptomatic staff screening for PHE 2020(e). The study authors for the outbreak evaluation study did not report the sensitivity value of 28.3% (95% CI 16.0% to 43.5%) in the publications but provided it to us on request.

All evaluations used naso- or oropharyngeal samples, two in viral transport medium (PHE 2020(a); PHE 2020(b)), and four using direct swab testing in compliance with manufacturer IFU (PHE 2020(c) [non-HCW tested]; PHE 2020(d) [HCW tested]; PHE 2020(d) [Lab tested]; PHE 2020(e)).

For studies reporting both sensitivity and specificity, average sensitivity and specificity were:

- 47.9% (95% CI 34.3% to 61.8%) and 99.8% (95% CI 99.5% to 99.9%) overall (n = 3; 2945 samples, 596 cases; Table 3); and
- 56.2% (95% CI 52.0% to 60.3%) and 99.8% (95% CI 99.5% to 99.9%) in symptomatic people (n = 2; 2794 samples, 550 cases; Table 4).

Only one of the three studies that reported both sensitivity and specificity was compliant with manufacturer IFU, the sensitivity and specificity were:

 57.5% (95% CI 52.3% to 62.6%) and 99.6 (95% CI 99.1%, 99.9%) overall (n = 1; 1676 samples, 372 cases).

Summary results from the four IFU-compliant evaluations were calculated as follows:

- average sensitivity across three evaluations of mainly symptomatic participants 69.1% (95% CI 58.3% to 78.2%; n = 3; 793 cases; Table 3; Table 4);
- average specificity from two evaluations of 99.7% (95% CI 99.3% to 99.9%; n = 2; 1842 samples with no SARS-CoV-2; Table 3).

Adding data from single-group evaluations in either RT-PCR-positive or RT-PCR-negative participants:

- average sensitivity was 59.0% (43.4%, 73.0%) (n = 5; 1015 cases)
- average specificity was 99.8% (99.5%, 99.9%) (n = 4; 2887 RT-PCR negative samples) (Table 4).

Results for each of the three IFU-compliant evaluations by test operator were (Figure 6):

- sensitivity of 57.5% (95% CI 52.3% to 62.6%) and specificity 99.6% (95% CI 99.1% to 99.9%), when the test was used by selftrained, non-healthcare workers (n = 1; 1676 samples, 372 cases; PHE 2020(c) [non-HCW tested]);
- sensitivity of 70.0% (95% CI 63.5% to 75.9%) when the test was used by healthcare workers (n = 1; 223 cases; PHE 2020(d) [HCW tested]);
- sensitivity of 78.8% (95% CI 72.4% to 84.3%) when the test was used by laboratory scientists (n = 1; 198 cases; PHE 2020(d) [Lab tested]).

Liming Bio-Products - StrongStep[®] COVID-19 Ag

We identified a single evaluation of the StrongStep assay in 19 symptomatic participants with nine SARS-CoV-2 positive samples ((Weitzel 2020 [B]; Figure 7). We could not identify the manufacturer's IFU for this assay. The study authors terminated the evaluation early following poor early results for this assay.

Sensitivity was 0% (95% Cl 0% to 33.6%) and specificity 90.0% (95% Cl 55.5% to 99.7%; 19 samples, 9 cases; Table 3; Table 4).

Quidel Corporation - SOFIA SARS Antigen

We identified a single evaluation of the SOFIA assay in symptomatic participants, including 64 samples with 32 SARS-CoV-2-positive cases (Porte 2020b [A]; Figure 7). The study used combined naso- and oropharyngeal swab samples in viral transport medium, therefore the evaluation was not compliant with the manufacturer IFU.

Sensitivity was 93.8% (95% CI 79.2% to 99.2%) and specificity was 96.9% (95% CI 83.8% to 99.9%; Table 3; Table 4).

RapiGEN - BIOCREDIT COVID-19 Ag

We identified six evaluations of the RapiGen BIOCREDIT assay; these reported data for 2170 samples, with 470 confirmed SARS-COV-2-positive cases (FIND 2020e (BR); FIND 2020e (DE); Mak 2020; Schildgen 2020 [A]; Shrestha 2020; Weitzel 2020 [A]; Figure 6). One laboratory-based study included cases only (n = 160). The other evaluations included participants from communitybased COVID-19 test centres (n = 2), emergency departments (n = 1), contact tracing (n = 1) or did not clearly report the setting (n = 1). Two studies included only symptomatic participants, two reported including both symptomatic and asymptomatic participants (mixed group) and one did not report symptom status. All evaluations apart from one (Schildgen 2020 [A]), tested nasopharyngeal or combined naso- or oropharyngeal samples.

Only three of the six evaluations complied with manufacturer IFU, with non-compliance because of the use of viral transport medium, or the type of swab tested.

The average sensitivity and specificity of the BIOCREDIT assay were:

- 63.3% (95% CI 45.7% to 78.0%) and 99.5% (95% CI 99.1 to 99.8) overall (n = 5; 2010 samples, 310 cases; Table 3);
- 58.4% (95% CI 36.3% to 77.5%) and 96.4% (95% CI 82.8% to 99.3%) in symptomatic people (n = 3; 608 samples, 206 cases);
- 63.2% (95% CI 21.7% to 91.4%) and 98.9% (95% CI 82.9% to 99.9%) in asymptomatic people (n = 2; 140 samples, 60 cases) (Table 4).

Restricting to IFU-compliant evaluations, average sensitivities and specificities were:

- 73.0% (95% CI 57.4% to 84.4%) and 99.8% (95% CI 99.4% to 99.9%) overall (n = 3; 1828 samples, 189 cases; Table 3);
- 74.4% (95% CI 65.5% to 82.0%) and 98.9% (95% CI 97.2% to 99.7%) in symptomatic people (n = 1; 476 samples, 117 cases);
- 85.1% (95% CI 71.7% to 93.8%) and 100% (95% CI 94.6% to 100%) in asymptomatic people (n = 1; 113 samples, 47 cases; Shrestha 2020; Table 4).

The addition of one evaluation that reported sensitivity only led to a decrease in overall average sensitivity of 5.6 percentage points (Mak 2020; Table 4).

Roche - SARS-CoV-2

According to the manufacturer IFU, the Roche SARS-CoV-2 assay is available under a partnership with SD Biosensor.

There was a single evaluation of the Roche assay using 73 bronchoalveolar lavage or throat wash samples (not covered by the IFU) in participants with mixed symptom status (Figure 7); 42 of the 73 samples were RT-PCR-positive (Schildgen 2020 [A]).

Overall, using bronchoalveolar lavage or throat wash samples, the sensitivity and specificity were 88.1% (95% CI 74.4% to 96.0%) and 19.4% (95% CI 7.5% to 37.5%) (73 samples, 42 cases; Table 3). Only the results for the subgroup of 50 throat wash samples could be separated by symptom status:

in symptomatic participants, sensitivity was 100% (95% CI 69.2% to 100%) and specificity was 7.7% (95% CI 0.2% to 36.0%) with 23 throat wash samples and 10 cases;

• in asymptomatic participants, sensitivity was 84.6% (95% CI 54.6% to 98.1%) and specificity was 14.3% (95% CI 1.8% to 42.8%), with 27 throat wash samples, 13 cases; Table 4).

Savant Biotech - Huaketai SARS-CoV-2 N Protein

We identified a single evaluation of the Huaketai assay in 109 symptomatic participants, using combined naso- or oropharyngeal swabs in viral transport medium (Weitzel 2020 [C]; Figure 7). We could not obtain the manufacturer IFU.

Sensitivity was 16.7% (95% CI 9.2% to 26.8%) and specificity was 100% (95% CI 88.8% to 100%; 109 samples, 78 cases; Table 3; Table 4).

SD Biosensor - STANDARD F COVID-19 Ag

We identified four evaluations of the STANDARD F assay; these reported data for 1552 samples, with 295 confirmed SARS-COV-2-positive cases (FIND 2020d (BR); FIND 2020d (DE); Liotti 2020; Porte 2020b [B]; Figure 6). Three evaluations included all or mainly symptomatic participants from community-based COVID-19 test centres and one was a laboratory-based study that did not provide details regarding symptom status.

All evaluations tested nasopharyngeal or combined nasoor oropharyngeal samples, however only two complied with manufacturer IFU. Reasons for non-compliance were the use of viral transport medium, or lack of information concerning viral transport medium.

The average sensitivity and specificity of the STANDARD F COVID-19 Ag assay were:

- 72.6% (95% CI 54.0% to 85.7%) and 97.5% (95% CI 96.4% to 98.2%) overall (n = 4; 1552 samples, 295 cases; Table 3);
- 78.0% (95% CI 71.6% to 83.3%) and 97.2% (95% CI 96.0% to 98.1%) in symptomatic people (n = 3; 1193 samples, 191 cases; Table 4).

No data for asymptomatic people were available.

Restricting to IFU-compliant evaluations, average sensitivity and specificity were:

 75.5% (95% CI 68.2% to 81.5%) and 97.2% (95% CI 96.0 to 98.1%), both studies in symptomatic people (n = 2; 1129 samples, 159 cases; Table 4).

SD Biosensor - STANDARD Q COVID-19 Ag

We identified six evaluations of the STANDARD Q assay; these reported data for 3480 samples, with 821 confirmed SARS-CoV-2-positive cases (Figure 6). Four evaluations included participants from community-based COVID-19 test centres, one was a laboratory-based study, and one included multiple settings. Four evaluations included symptomatic or mainly symptomatic participants, and two included mixed symptomatic and asymptomatic participants.

All evaluations tested nasopharyngeal or combined naso- or oropharyngeal samples, four of which were compliant with manufacturer's IFUs, the other two used samples in viral transport medium.

The average sensitivity and specificity of the STANDARD Q COVID-19 Ag assay were:

- 79.3% (95% CI 69.6% to 86.6%) and 98.5% (95% CI 97.9% to 98.9%) overall (n = 6; 3480 samples, 821 cases; Table 3);
- 80.1% (95% CI 68.5% to 88.1%) and 98.1% (95% CI 97.4% to 98.6%) in symptomatic people (n = 5; 2760 samples, 731 cases); and
- 61.1% (95% CI 37.9% to 80.2%) and 99.6% (95% CI 97.3% to 99.9%) in asymptomatic people (n = 2; 272 samples, 18 cases; Table 4).

Restricting to IFU-compliant evaluations, average sensitivities and specificities were:

- 85.8% (95% CI 80.5% to 89.8%) and 99.2% (95% CI 98.2% to 99.6%) overall (n = 4; 2522 samples, 421 cases; Table 3);
- 88.1% (95% CI 84.2% to 91.1%) and 99.1% (95% CI 97.8% to 99.6%) in symptomatic people (n = 3; 1947 samples, 336 cases); and
- 69.2% (95% CI 38.6% to 90.9%) and 99.1% (95% CI 95.2% to 100%) in asymptomatic people (n = 1; 127 samples, 13 cases; Table 4).

Shenzhen Bioeasy Biotech - 2019-nCoV Ag

We included three evaluations of the Bioeasy FIA; these included 965 samples with 177 SARS-CoV-2-positive cases ((Kruger 2020(a); Porte 2020a; Weitzel 2020 [D]; Figure 6). Studies were conducted in hospital emergency departments (n = 2) or a community COVID-19 test centre (n = 1). Participants in studies were all symptomatic or mainly symptomatic.

Two evaluations used combined naso- or oropharyngeal swabs and one tested either nasopharyngeal or oropharyngeal swabs. Two evaluations used swabs in viral transport medium, which was not documented as suitable for use on the manufacturer IFU.

The average sensitivity and specificity of the Shenzhen Bioeasy assay were :

86.2% (95% CI 72.4% to 93.7%) and 93.8 (95% CI 91.9% to 95.3%) overall (all symptomatic; n = 3; 965 samples, 177 cases; Table 3; Table 4).

The single IFU-compliant evaluation Kruger 2020(a) reported sensitivity of 66.7% (95% CI 38.4% to 88.2%) and specificity of 93.1% (95% CI 91.0% to 94.9%; 727 samples, 15 cases).

We also included an additional study that reported the development of this assay but we did not pool data with the other evaluations as it was a development and not a validation study (Diao 2020; Figure 7). Sensitivity was 67.8% (95% CI 61.0% to 74.1%) and specificity was 100% (95% CI 88.8% to 100%; 239 samples, 208 cases).

Direct test comparisons

Three studies reported direct comparisons of different antigen assays in naso- or oropharyngeal samples; however none of the studies had any assay comparisons in common. All three studies utilised swabs in viral transport medium and all were conducted in symptomatic participants. We cannot derive any clear conclusions about comparative performance of tests from these studies. Figure 8 shows variable diagnostic performance between and to some extent within studies. Four of the five assays in Fourati 2020 [A] demonstrated sensitivities in the range of 55% to 62% (SD Biosensor STANDARD Q, Abbott Panbio Covid-19 Ag, Biosynex COVID-19 Ag, AAZ – COVID-VIRO), with one outlier (Coris Bioconcept – Covid-19 Ag) at 35% (maximum of 297 cases). Specificity was 100% for all assays apart from SD Biosensor SDQ (specificity 93%; 337 pre-pandemic samples).

In Porte 2020b [A] (32 cases) both assays had sensitivities over 90% (SD Biosensor STANDARD F and Quidel Sofia SARS Antigen), with specificities 97% (32 non-COVID-19 samples)

Weitzel 2020 [A] observed a range in assay sensitivities from 0% for the Liming Bio-Products assay (based on only nine cases), to 17% (for Savant Biotech – Huaketai SARS-CoV-2 N), 62% (RapiGEN – BIOCREDIT COVID-19 Ag) and 85% for Shenzhen Bioeasy Biotech – 2019 nCov Ag (78 to 80 cases for the latter three assays). Specificities were 100% for all assays (based on 30 to 31 samples) apart from the one from Liming Bio-Products (specificity 90% based on 10 samples).

Accuracy of rapid molecular tests overall and by subgroup

Average sensitivity and specificity for the 29 rapid molecular test evaluations that included samples with and without SARS-CoV-2, were 95.1% (95% CI 90.5% to 97.6%) and 98.8% (95% CI 98.3% to 99.2%; 4351 samples, 1781 with confirmed SARS-CoV-2; Table 5). Adding the three 'cases only' studies made little difference to the average sensitivity (95.5%, 95% CI 91.5% to 97.7%; 1973 cases).

Figure 9 demonstrates heterogeneity in sensitivity estimates (ranging from 57% to 100%), with consistently high specificities (92% to 100%, but with upper limits of 95% CIs of 99% or 100% in every study).

Subgroup analyses by viral load

We extracted sensitivity data according to viral load from 10 evaluations of molecular tests, six of which reported data at a Ct threshold for higher viral load of 30 or less (Jokela 2020; Lieberman 2020; Mitchell 2020; Smithgall 2020 [A]; Smithgall 2020 [B]; Wolters 2020), four using Xpert Xpress and two using ID NOW. (Appendix 16)

All sensitivity estimates for the higher viral load subgroups were 100% (based on 204 samples with confirmed SARS-CoV-2), with a 95% CI for the average of 98.2% to 100%. For the lower viral load group, average sensitivity was 95.6% (95% CI 55.7% to 99.7%) (149 samples with confirmed SARS-CoV-2; Table 5).

We observed a similar pattern for the studies using alternative Ct thresholds to define higher and lower viral load (Appendix 17).

Subgroup analysis by study design

We did not observe any clear differences in average sensitivity or specificity when studies were separated by study design (2899 samples and 976 cases in 18 single-group studies and 1265 samples and 718 cases in nine two-group studies; Table 5; Appendix 17). Average sensitivity was higher in two-group studies (97.2%, 95% CI 90.7% to 99.2%) compared to single-group studies (93.2%, 95% CI 85.5% to 97.0%); a difference of 4.0 percentage points (95% CI from 2.2 percentage points lower to 10.1 higher). Average specificities had almost identical point estimates at 99.4% (95% CI 98.4 to 99.8%) and 99.3% (95% CI 96.5% to 99.8%) respectively (Table 5).

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

Abbott – ID NOW

Thirteen studies evaluated the ID NOW assay, with 1949 samples and 730 confirmed SARS-CoV-2 cases; one study included only SARS-CoV-2-positive cases (n = 36; Figure 10). Seven evaluations were laboratory-based, three recruited participants from emergency department settings and three were conducted in multiple settings. Seven studies included only symptomatic participants, two included both symptomatic and asymptomatic people, and four did not report symptom status.

Eleven evaluations used nasopharyngeal or nasal swab samples, one was conducted using saliva samples and one did not specify the sample type. Only four evaluations were compliant with manufacturer IFUs; lack of compliance was based on the use of viral transport medium, sample type, and interval between sample collection and testing.

Pooled analyses demonstrated average sensitivity and specificity of:

- 78.6% (95% CI 73.7% to 82.8%) and 99.8% (95% CI 99.2% to 99.9%) overall (n = 12; 1853 samples, 634 cases); and
- 73.0% (95% CI 66.8% to 78.4%) and 99.7% (95% CI 98.7% to 99.9%), restricted to evaluations that were compliant with the manufacturer's IFU (n = 4; 812 samples, 222 cases; Table 5).

Average sensitivity increased to 81.5% (95% CI 75.2% to 86.5%), with the addition of the cases only study (730 cases; Rhoads 2020).

Cepheid Inc – Xpert Xpress

The Xpert Xpress assay was evaluated in 15 studies using respiratory specimens, with 1781 samples and 1001 confirmed SARS-CoV-2 cases; two of the studies included only SARS-CoV-2 positive cases (n = 90; Figure 10). Thirteen evaluations were laboratory-based, one recruited participants from emergency department settings and one included samples from hospital inpatients. Three studies included only symptomatic participants, one included both symptomatic and asymptomatic people (mixed symptom status), and 11 did not report symptom status.

Fourteen evaluations used nasopharyngeal, oropharyngeal or nasal swab samples, and one was conducted using throat saliva or lower respiratory samples. Only three evaluations were compliant with manufacturer IFUs. Lack of compliance with the IFU was because of the use of frozen samples (n=8), or sample type (n=1) or concerns about the timing between sample collection and testing (n=3).

Pooled analyses demonstrated average sensitivity and specificity of:

- 99.1% (95% CI 97.7% to 99.7%) and 97.9% (95% CI 94.6 % to 99.2%) overall (n = 13; 1691 samples, 911 with confirmed SARS-CoV-2);
- 100% (95% CI 88.1% to 100%) and 97.2% (95% CI 89.4%, 99.3%), restricted to evaluations that were compliant with the manufacturer's IFU (n = 2; 100 samples, 29 cases; Table 5)

Average sensitivity did not change with addition of two cases-only studies (99.1%, 95% CI 97.8% to 99.6%; n = 15; 730 cases; Broder 2020; Chen 2020a).

One additional study considered accuracy in non-respiratory samples using Xpert Xpress (Szymczak 2020). Sensitivity in stool samples obtained up to 33 days after symptom onset was 93.1% (95% CI 77.2% to 99.1%) and specificity was 96.0% (95% CI 86.3% to 99.5%; 79 samples, 29 cases).

Comparison of ID NOW with Xpert Xpress

Comparing the overall pooled results between ID NOW and Xpert Xpress, the average sensitivity of Xpert Xpress was 19.8 (95% CI 14.9 to 24.7) percentage points higher than that of ID NOW (P < 0.0001; Table 5).

The average specificity of Xpert Xpress was marginally lower than that of ID NOW, a difference of -1.9 percentage points (95% CI -3.8 to -0.1).

DNAnudge – COVID Nudge

We included one evaluation of COVID Nudge with a total of 386 participants and 71 SARS-CoV-2-positive cases (Gibani 2020; Figure 10). Participants were recruited from multiple settings including hospital inpatients (n = 88), accident and emergency (n = 15) and healthcare workers and their families (n = 280). All participants were symptomatic and direct testing of nasopharyngeal samples was used (within manufacturer IFU).

The sensitivity of the COVID Nudge assay was 94.4% (95% CI 86.2 to 98.4%) and specificity was 100% (95% CI 98.8% to 100%; 386 samples and 71 cases; Table 5).

Diagnostics for the Real World (DRW) - SAMBA II

We included two evaluations of SAMBA II with 321 samples (121 with confirmed SARS-CoV-2; Figure 10). All participants were symptomatic. One study conducted direct testing of combined naso- or oropharyngeal samples from hospital inpatients and the other obtained combined naso- or oropharyngeal samples in viral transport medium from Public Health England. It was not reported whether the PHE samples were stored or frozen prior to testing so we could not determine whether they complied with the IFU for the assay.

The average sensitivity and specificity of SAMBA-II were 96.0% (95% CI 81.1% to 99.3%) and 97.0% (95% CI 93.5% to 98.6%; 2 studies; 321 samples, 121 with confirmed SARS-CoV-2; Table 5).

In the IFU-compliant evaluation, sensitivity was 87.9% (95% CI 71.8% to 96.6%) and specificity was 97.4% (95% CI 92.6% to 99.5%; 149 samples, 33 cases; Collier 2020; Table 5).

Mesa Biotech – Accula

We included one evaluation of the Accula assay with a total of 100 samples (50 SARS-CoV-2 positive; Hogan 2020; Figure 10). The study was laboratory-based and symptom status was not reported.

The study used nasopharyngeal samples in viral transport medium or saline, therefore the evaluation was not compliant with IFU requirements.

The sensitivity and specificity of the Accula test were 68.0% (95% CI 53.3% to 80.5%) and 100% (95% CI 92.9% to 100%; 100 samples, 50 cases; Table 5).

Sensitivity analysis of the impact of discrepant analysis

Six evaluations of molecular tests (in 1533 samples) reported results before and after discrepant analysis where selected samples were re-tested with either the same (Collier 2020; Harrington 2020; Moran 2020; Stevens 2020), or an alternative RT-PCR assay (Assennato 2020; Loeffelholz 2020). Four studies also reported retesting of samples with the index test (Assennato 2020; Collier 2020; Harrington 2020; Moran 2020; Appendix 16; Appendix 17).

Discrepant analysis reduces the number of samples deemed to be false negative or false positive errors. Discrepant analysis reduced the false negative proportion (1-sensitivity) from 2.1% to 0.8% and the false positive rate (1-specificity) from 2.2% to 0.4%. Three of the five studies reporting initially false positive results reported zero false positives after sample re-testing and one reported a drop in false positives from 11 to 3 (Loeffelholz 2020; Appendix 16). Three of the four studies that reported re-testing of initially false negative results reported reclassification as true negative on re-testing, and in the other the single false negative remained as a false negative. Given the bias inherent in choosing the reference test dependent on the observed results, we caution against these findings.

An additional study tested all samples with two different RT-PCR assays, and hence used a more accurate reference standard in all samples, not just samples with discrepant results (Moore 2020). Six initial true negatives were reclassified as false negatives after the second RT-PCR. Had discrepant analysis been undertaken these misclassifications would have been missed, further underlining the methodological flaws inherent to discrepant analysis.

Other sources of heterogeneity

We also planned to evaluate the effect of sample type and reference standard.

For sample type, the use of variable combinations of sample types with or without viral transport media created numerous sparse subgroups by sample type (Appendix 18). Instead we considered study compliance with manufacturer IFU requirements which is a more pragmatic classification.

All studies used RT-PCR alone as the reference standard for diagnosing SARS-CoV-2 infection.

Publication bias

We did not formally test for publication bias evident in the pattern of results, but did note that the identity of tests not meeting the PHE assessment criteria were not reported due to confidentiality agreements (PHE 2020(a)).

DISCUSSION

This is the second iteration of a Cochrane living review summarising the accuracy of point-of-care antigen and molecular tests for detecting current SARS-CoV-2 infection. This version of the review is based on published journal articles or studies available as preprints from 1 January 2020 up until 30 September 2020. In addition, we also included evaluations of antigen assays that were available as independent national reference laboratory publications or that were co-ordinated and published by FIND, and journal articles that were listed on the Diagnostics Global Health website to 16 November 2020.

Summary of main results

We included data from 77 studies using respiratory specimens, including 24,418 samples (7484 samples with confirmed SARS-CoV-2), and one study of faecal specimens (79 samples, 29 with confirmed SARS-CoV-2). Forty-eight studies (reporting 58 test evaluations) considered antigen tests; 30 studies (reporting 33 test evaluations) considered rapid molecular tests, including the single study (evaluation) in faecal samples. Key findings are presented in the Summary of findings 1.

We summarise six key findings from this review:

1. Despite a considerable increase in the number of studies evaluating point-of-care tests, particularly antigen tests, there are still no published or preprint reports of accuracy for a significant number of commercially produced point-of-care tests. This review located evaluations for 16 antigen tests (three of which we could not identify as available for purchase) and five molecular assays. These represent a small proportion of assays currently on the market (118 commercialised antigen tests and 53 molecular assays).

2. The new studies have more robust and appropriate study designs compared to those in the first version of this review. Particularly for antigen tests where there are now studies recruiting participants from community-based COVID-19 testing clinics. Reporting of key details, such as settings and symptom status have improved, and studies are now evaluating direct swab testing as would occur in a point-of-care setting. However, concerns about risk of bias and applicability of results remain, and further improvements in study methods and reporting are needed before strong conclusions can be drawn about the accuracy of many antigen and molecular tests reviewed here. As it is not known whether these limitations will lead to over- or underestimates of test accuracy, estimates should be cautiously interpreted in context of their methodological limitations and the settings in which they were conducted. More direct comparisons of test brands are needed, with evaluations undertaken in the intended use settings for these tests.

Particular methodological concerns include the use of deliberate sampling according to known presence or absence of SARS-CoV-2 infection; use of anonymised samples submitted to laboratories for routine RT-PCR testing (with no setting or participant details); and no information on symptoms or time from symptom onset. Differences in case-mix related to symptomatic status, time post-symptom onset and distribution of viral load are likely to have contributed to the observed variation in accuracy.

RT-PCR was the reference standard in all studies - no study defined the presence of COVID-19 using clinical or radiological features in the absence of a negative RT-PCR result.

3. Studies frequently did not follow the manufacturer's instructions or did not use the test at the point of care. Fewer than half conducted the tests according to the manufacturers' IFU (41% (37/91); 29/58 antigen test evaluations and 8/33 molecular test evaluations). Reasons for non-compliance included use of frozen samples, use of viral transport media, or lengthy intervals between sample collection and testing. Almost a third of studies (23/78) undertook on-site, direct swab testing immediately or within an hour of sample collection; trained laboratory staff conducted tests in 16 (21%) studies, and 31 (40%) studies did not clearly describe the test operator and setting for the test procedure but we inferred

that tests were carried out in a centralised laboratory setting, for example based on reported delays between collection and testing or reported use of archived or frozen samples.

4. For antigen test evaluations in symptomatic participants, we observed considerable heterogeneity in sensitivities (and to a lesser extent the specificities). Whilst the average sensitivity was 72.0% (95% CI 63.7% to 79.0%) and specificity was 99.5% (95% CI 98.5% to 99.8%), average sensitivity decreased with time since onset of symptoms, being higher in the first week (78.3%, 95% CI 71.1% to 84.1%) than when done later (51.095% CI 40.8% to 61.0%). Sensitivity was high in those with higher viral loads defined by Ct values \leq 25 (94.5% 95% Cl 91.0% to 96.7%) compared to those with lower viral loads (40.7%, 95% CI 31.8% to 50.3%). Focusing on studies that used the test in accordance with the manufacturer's instructions, sensitivities for different brands varied from 34% to 96% (either based on pooled results or single studies). WHO have set a minimum 'acceptable' sensitivity requirement of 80%, and acceptable and ideal (or 'desirable') specificity requirements of 97% and 99% respectively (WHO 2020c). Only one assay (SD Biosensor STANDARD Q) met the WHO acceptable criterion for sensitivity based on pooled results of several studies. One further test (BIONOTE NowCheck) also met the acceptable sensitivity criterion, but only one study evaluated it. Abbott Panbio met the sensitivity criterion in individual studies but not overall. The acceptable performance criterion of 97% specificity was also met for all three tests, and two tests met the desirable criterion of more than 99% specificity (Abbott Panbio and SD Biosensor STANDARD Q).

Considerable heterogeneity in sensitivities remained after restricting analyses by test brand and symptom status, suggesting an effect not only from participant characteristics but from setting, sample type and collection method, sample storage and preparation, and testing procedures that cannot be easily unpicked. The PHE studies included in this review allow some consideration of the effect of test operator experience on the accuracy of the Innova test although different samples were tested by each test operator such that only an indirect comparison of sensitivity can be made. Sensitivity increased from 57.5% (95% CI 52.3%, 62.6%; 372 samples) when testing was conducted on-site by trained non-healthcare workers (PHE 2020(c) [non-HCW tested]), to 70.0% (95% CI 63.5% to 75.9%; 223 samples) in samples tested onsite by healthcare workers ((PHE 2020(d) [HCW tested]), to 78.8% (95% CI 72.4% to 84.3%; 198 samples) for those tested by laboratory scientists (PHE 2020(d) [Lab tested]). The effect of test operator on accuracy has been observed for rapid diagnostic tests for other infectious diseases such as malaria (Boyce 2018; Landier 2018), and is worthy of further investigation for diagnosis of SARS-CoV-2.

5. Twelve studies evaluated the accuracy of antigen tests in asymptomatic people for detection of SARS-CoV-2 infection defined by PCR status. As discussed, this does not address the issue of whether the test is identifying those who are infectious (as there is no reference standard that can be used). The average sensitivity for detecting infection in asymptomatic participants was 58.1% (95% CI 40.2% to 74.1%) with specificity of 98.9% (95% CI 93.6% to 99.8%), both lower than in symptomatic people. Only half of studies reported clearly defined asymptomatic cohorts (e.g. preventive screening in the general population (n = 1), in returning travellers (n = 1), or in contacts of confirmed cases (n = 4)), the other six reported asymptomatic subgroups from mixed symptom

cohorts. Only one of the 12 studies provided data by viral load (Fenollar 2020(b)); 5% (1/22) of RT-PCR-positive samples had a Ct value of 25 or less, but 50% (11/22) had Ct values of 30 or less. No information on time after exposure to infection was reported.

6. For rapid molecular assays there were differences between test brands. Most data were for ID NOW and Xpert Xpress assays; average sensitivity for ID NOW was 78.6% (95% CI 73.7% to 82.8%) and Xpert Xpress 99.1% (95% CI 97.7% to 99.7%). Specificity for ID NOW was 99.8% (95% CI 99.23%, 99.9%) and Xpert Xpress 97.9% (95% CI 94.6% to 99.2%). These differences are beyond those expected by chance (P < 0.0001).

We were not able to investigate the effects of symptomatic status, or time from symptom onset: 12/29 were from symptomatic populations, three from 'mixed' symptomatic and asymptomatic populations (percentage from each group not reported), and the remaining 14 evaluations provided no information on symptom status (2/14 recruited from A&E and 12 were laboratory-based). These and other methodological limitations in the studies mean that we do not know how the assays would perform in any specific clinical setting when used in people suspected of having SARS-CoV-2 infection on the basis of symptoms, or of exposure to a confirmed case in the absence of symptoms. It is likely however that some difference in sensitivity between ID NOW and Xpert Xpress would be maintained in the absence of bias. The difference in specificity between the tests is small (ID NOW being 1.9% more specific compared to Xpert Xpress), but potentially important especially if used in a low-prevalence setting. However, this difference in specificity would not be an issue should testpositives be confirmed by a laboratory-based RT-PCR assay.

7. There are proposals for repeated use of antigen tests in different asymptomatic groups, such as school children and staff, hospital and care home workers, and even the general public, with a variety of different testing strategies. We found no data or studies evaluating the accuracy of any of these serial screening strategies.

We did not formally compare antigen with molecular assays because there were no head-to-head comparisons of the two test types. Instead, we illustrate predicted numbers of true positives, false positives, false negatives and true negatives, applying summary estimates of test accuracy to a hypothetical cohort of people suspected of SARS-CoV-2 infection across a range in prevalence of SARS-CoV-2 infection (Summary of findings 1). For both antigen and molecular assays, we only use summary data from evaluations conducted in accordance with manufacturers' IFUs, and for antigen tests we used separate results from symptomatic and asymptomatic participants.

Illustration of predicted effect of antigen testing by symptom status

For antigen test evaluations in symptomatic people, we selected three assays representing the range in observed average sensitivities: Coris Bioconcept COVID-19 Ag Respi-Strip (34.1% to 95% Cl 29.7% to 38.8%), Abbott - Panbio Covid-19 Ag (75.1% to 95% Cl 57.3% to 87.1%); and SD Biosensor - STANDARD Q COVID-19 Ag (88.1% to 95% Cl 84.2% to 91.1%). Average specificities for the same three assays were 100% (95% Cl 99.0% to 100%) to 99.5% (95% Cl 98.7% to 99.8%) and 99.1% (95% Cl 97.8% to 99.6%) respectively. Applied to a cohort of 1000 people with signs and symptoms of

COVID-19, in whom 50 people had confirmed infection (prevalence of 5%), for the three assays above we predicted that:

- 17, 43 or 53 people would have a positive test result, of which 0, 5 and 9 would be false positives (positive predictive values (PPV) 100%, 88.4% and 83.0%, respectively), and
- 33, 12 and 6 people with negative test results would be falsely negative (negative predictive values (NPV) 96.6%, 98.7%, and 99.4%).

Increasing the prevalence to 10% or 20%, increases PPV and decreases NPV. As there is considerable heterogeneity in the estimates of sensitivity, the values observed in practice could vary considerably from these figures as shown by the estimates derived from the confidence intervals (Summary of findings 1).

For antigen test evaluations in asymptomatic participants there was considerably less available data from IFU-compliant evaluations. We selected the same three exemplars, average sensitivities for identification of any infection (whether infectious or not) were lower than for symptomatic populations: 28.6% (95% CI 8.4% to 58.1%) for the Coris Bioconcept assay; 48.9% (95% CI 35.1% to 62.9%) for the Abbott assay; and 69.2% (95% CI 38.6% to 90.9%) for the SD Biosensor assay. Average specificities for the same three assays were: 100% (95% CI 88.8% to 100%), 98.1% (95% CI 96.3% to 99.1%), and 99.1% (95% CI 95.2% to 100%).

Applying the average values to a larger cohort of 10,000 people asymptomatic for COVID-19 and with a lower prevalence of 0.5% in whom 50 people had confirmed infection (infectious or not):

- 14, 213 or 125 individuals would have a positive test result of which 0, 189 and 90 would be false positives (PPVs of 100%, 11% and 28%, respectively), and
- 36, 26 and 15 people with negative test results would be falsely negative (NPVs 99.6%, 99.7%, and 99.8%).

We derived the summary estimates used in these calculations from asymptomatic participants identified for testing in a number of scenarios and they cannot be directly translated to a particular setting, such as mass screening, for example. The confidence intervals for the average estimates used in these calculations are also extremely wide for both sensitivities and specificities, such that the numbers of false positives and false negatives observed in practice could differ substantially from these figures. Increasing the prevalence of confirmed SARS-CoV-2 infection to 1% or 2% makes little difference to the absolute number of false positive results for these assays, but has a large relative effect when considered in relation to the number of positive test results (PPVs for the Abbott and SD Biosensor assays increasing to 40% and 61% at 2% prevalence).

Illustration of predicted effect of rapid molecular tests for symptomatic testing

For molecular assays, data from IFU-compliant evaluations were available for four of the five assays: ID NOW (Abbott Laboratories), Xpert Xpress (Cepheid Inc), SAMBA II (Diagnostics for the Real World) and COVID Nudge (DNAnudge). Average sensitivities were derived as 73.0% (95% CI 66.8% to 78.4%), 100% (95% CI 88.1% to 100%), 87.9% (95% CI 71.8% to 96.6%) and 94.4% (95% CI 86.2% to 98.4%). Average specificities were 99.7% (95% CI 98.7% to 99.9%),

97.2% (95% CI 89.4% to 99.3%), 97.4% (95% CI 92.6% to 99.5%) and 100% (95% CI 98.8% to 100%), respectively (Summary of findings 1).

Data by symptom status for these assays were very limited, therefore we assumed that the intended use is most likely to be for diagnosis of acute infection in symptomatic individuals and have applied the average estimates of accuracy to a hypothetical cohort of 1000 people, at prevalences of 5%, 10% and 20% (Summary of findings 1). If 50 of 1000 people had confirmed infection (5% prevalence):

- 40, 77, 69 and 47 individuals would have a positive test result of which 3, 27, 25 or 0 would be false positive (PPVs of 93.0%, 64.9%, 63.8%, and 100% respectively).
- 14, 0, 6 and 3 people with negative test results would be falsely negative (NPVs 98.6%, 100%, 99.4% and 99.7%).

Increasing the prevalence of confirmed SARS-CoV-2 infection to 10% or 20% has a large relative effect when considered in relation to the number of positive test results for both Xpert Xpress and SAMBA II (PPVs were 64.9% and 63.8% at 5% prevalence compared to 90.1% and 89.3% at 20% prevalence). Less variation in PPV was observed for ID NOW and COVID-Nudge because of the higher observed specificities. The NPV for the molecular assays is not affected to the same degree by these prevalence changes because of their relatively high sensitivities and the relatively low-prevalence scenarios being considered.

Across all exemplar assays in the Summary of findings 1, we observed the widest variation in NPV for the Coris Bioconcept antigen assay in symptomatic participants (86% to 97%), demonstrating that even in a low-prevalence setting, tests with poor sensitivity can have a considerable impact on the level of confidence that can be had in a negative test result.

Strengths and weaknesses of the review

Our review used a broad search screening all articles concerning COVID-19 or SARS-CoV-2. We undertook all screening and eligibility assessments, QUADAS-2 assessments (Whiting 2011), and data extraction of study findings independently and in duplicate. Although it is possible that the use of artificial intelligence text analysis to identify studies most relevant to diagnostic questions may have led to some eligible studies being missed, we believe that the multi-stranded search strategy used will have identified most if not all relevant literature. Whilst we have reasonable confidence in the completeness and accuracy of the findings up until the search date, should errors be noted please inform us at coviddta@contacts.bham.ac.uk so that we can verify and correct in our next update.

We undertook a careful assessment of sample preparation and biosafety requirements as well as time to test result, to ensure that included tests were suitable for use at the point of care. The application of these index test criteria led to the exclusion of 39 of the 85 studies that we excluded on the basis of the index tests evaluated. Evaluations of alternative laboratory-based molecular technologies are under consideration for inclusion in another review in our series of Cochrane COVID-19 diagnostic test accuracy reviews. Furthermore, for this iteration of the review, we explicitly considered whether the test evaluations were conducted in accordance with the manufacturer IFU, regarding the sample

types used, the use of viral transport medium and the permitted time between sample collection and testing.

We did not consider any manufacturer statements on the intended use of the tests by population, but we are aware that some IFUs recommend testing only in symptomatic people and within certain time frames after symptom onset (e.g. the Innova assay). Where possible, however, we did provide data separately for symptomatic and asymptomatic participants and identified clear trends towards lower sensitivities in asymptomatic individuals for detection of infection. We were unable to assess the accuracy of antigen tests for identification of infectious individuals, as there is no established reference standard for infectiousness (and it seems unlikely that one will ever be established). We have presented results by Ct value where it has been reported by the individual studies. We recognise the limitations from this approach, and given the extent to which RT-PCR Ct values vary between assays (Vogels 2020), and between laboratories, we strongly caution against the direct application of our results in high and low Ct value subgroups to any particular clinical context. There is no 'step change' in 'infectiousness' according to any fixed Ct value; increasing numbers of studies demonstrate successful viral culture in individuals considered to have 'low' viral load (Jaafar 2020; Singanayagam 2020), and, more importantly, that transmission of infection does occur from index cases with low RT-PCR Ct values (Lee 2021; Marks 2021). Ultimately, viral load on its own is only one factor influencing an individual's ability to transmit infection, 'infectiousness' being modified by host factors such as the health of an individual's immune system or presence of comorbidities, and environmental risk factors including closeness and length of contact with others.

Weaknesses of the review primarily reflect the weaknesses in the primary studies and their reporting. Although study quality improved in comparison to the first iteration of this review, many studies continue to omit descriptions of participants, and key aspects of study design and execution. In order to include data for all tests in pooled analyses we had to include some samples multiple times. We have been explicit about these issues where they arose. It is possible that eligible studies have been missed by our search strategy however we believe the risk to be very low considering our broad approach to identification of literature. Despite our best efforts to be as comprehensive as possible, new evaluations are continuously becoming available and it is impossible for any published and peer-reviewed systematic review to be fully up to date.

Around a quarter (18/78) of the studies we have included are currently only available as preprints, and as yet, have not undergone peer review. As published versions of these studies are identified in the future, we will double-check study descriptions, methods and findings, and update the review as required.

Applicability of findings to the review question

There are an increasing number of roles and testing strategies for which antigen and rapid molecular assays are considered, and it is likely that the performance of these tests needs to be considered separately for each of the use cases.

Our review shows that antigen tests do not appear to perform as well in asymptomatic populations compared to symptomatic populations for detecting infection. The amount of available data for asymptomatic populations is less than that from symptomatic

populations and is also based on asymptomatic individuals tested in a range of scenarios, from preventive or targeted screening, to contact tracing or testing at dedicated COVID-19 test centres, which may explain some of the observed variability. It is also not clear whether individuals in these studies were truly cases of asymptomatic infection as opposed to pre- or postsymptomatic, or were even mildly symptomatic and mislabelled as asymptomatic. Incomplete symptom assessment and lack of adequate follow-up to identify subsequent development of symptoms or previous history of symptoms can all contribute to inappropriate classification of individuals as asymptomatic infection (Meyerowitz 2020). As the studies in our review did not systematically attempt to identify pre- or post-symptomatic individuals, it may be more appropriate to consider the estimates for test accuracy for asymptomatic populations as primarily representing accuracy in those without clearly defined symptoms at the time of testing.

We are aware that several important studies in asymptomatic individuals have been reported since the close of our search. In mass screening in Liverpool, Innova was positive in 28 of 70 PCRdetected cases (sensitivity for infection 40.0%, 95% CI 28.5% to 52.4%) and 26 of 39 with Ct values less than 25 (sensitivity 66.7%, 95% CI 49.8% to 80.9%). Screening University of Birmingham students found 2 of 7185 students positive with Innova, and estimated sensitivity of 3.2% (95% CI 0.6% to 15.6%) for detecting any infection, 9.1% (95% CI 1.0% to 49.1%) for Ct values less than 30 and 100% (95% CI 15.8% to 100%) for Ct less than 25 (Ferguson 2020). BinaxNOW (which uses the same test strip as PanBio) has been tested in asymptomatic groups: in San Francisco the test detected 7 of 11 PCR-positive cases (sensitivity 63.6%, 95% CI 30.8% to 89.1%), and 6 of 6 with Ct values less than 30 (100%, 95% CI 54.1% to 100%; Pilarowski 2021); in a drive-through centre in Massachusetts it detected the virus in 70 of 107 in adults (sensitivity 65.4%, 95% CI 55.6 to 74.4) and 40 of 57 in children (70.2%, 95% CI 56.6% to 81.6%)); no breakdown by viral load is available (Pollock 2020). The specificity of the tests in all studies has remained high (above 99%). This selection of results is not based on a systematic search (this will occur in the next update) but these results suggest that emerging evidence is illustrating a range of sensitivity values for the ability of the tests to detect infection, with high detection rates only in groups with very high viral loads.

Given the superior test performance characteristics for symptomatic populations in the first week of symptoms and in those with higher viral loads, the observed poorer performance in those without symptoms is perhaps not surprising. Evidence suggests that higher viral loads are observed in the first week of illness, beginning two days prior to the development of symptoms (Cevik 2021). Viral load patterns in asymptomatic people are less clear but similarly high titers of SARS-CoV-2 have been observed at the onset of infection with a suggestion of faster clearance (Cevik 2021). However, variation in viral trajectories means that even if an asymptomatic person can identify a clear contact with a confirmed case of SARS-CoV-2 infection, it is not possible to pinpoint when (or even if) that individual will have a sufficient viral load to be detected on antigen testing. A serial testing policy would be likely to identify at least some infected asymptomatic contacts, but comes at the cost of increased numbers of false positives, especially in lowprevalence settings. There were no evaluations of serial testing in any of the studies.

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

For molecular tests, we observed a lack of studies undertaken in intended use settings, with most data being from laboratory testing. Although more evidence is available for accuracy in symptomatic people, applicability issues regarding the way in which the tests are carried out and in how cases of SARS-CoV-2 infection are defined remain, and it is not yet possible to determine how tests will perform in practice.

We recommend caution in applying the results outside of the individual study (or closely related) contexts and use case scenarios.

AUTHORS' CONCLUSIONS

Implications for practice

We consider the implications for practice for this review separately for symptomatic and for asymptomatic testing.

In the Role of index test(s) section, we suggested that for symptomatic individuals, and if sufficiently accurate, point-of-care testing could be used either to replace laboratory-based RT-PCR or as a triage to RT-PCR. As point-of-care tests are more accessible and provide a result more quickly than RT-PCR, theoretically their use may increase detection and speed up isolation and contact-tracing, leading to reduction in disease spread and reduce the burden on laboratory services.

The evidence included to date suggests that:

1. For diagnosis in symptomatic individuals in the first few days of symptoms, the most accurate rapid antigen tests are a useful alternative to laboratory-based RT-PCR where immediate results are required for timely patient management or where there are significant logistical or financial challenges in delivering RT-PCR in a timely manner. Rapid antigen tests are only sufficiently sensitive in the first week since onset of symptoms.

Antigen tests vary in sensitivity, and only those shown to meet appropriate criteria, such as WHO's priority target product profiles for COVID-19 diagnostics (i.e. sensitivity \geq 80% and specificity \geq 97%; WHO 2020c), could be considered as a rational substitute for RT-PCR.

Tests had high specificity, thus in symptomatic populations (where prevalence is likely to be high) the risk of false positives is low. At 80% sensitivity compared to RT-PCR, the probability that infected individuals are missed is 20% higher than for RT-PCR. Thus the possibility of false negative results should be considered in those with a high clinical suspicion of COVID-19, particularly if tested several days after onset of symptoms when viral load levels may have fallen.

2. Rapid antigen tests may be used simultaneously in combination with RT-PCR for symptomatic people, particularly where RT-PCR turn-around times are slow, to exploit the benefits of earlier results and consequent contact-tracing and isolation. Given the risk of false-negative results, isolation may be required until RT-PCRnegative results are obtained. Similarly, for investigation of local outbreaks, rapid antigen testing in a clearly defined population may establish cases and contacts that require isolation whilst awaiting results from RT-PCR. In other circumstances rapid antigen tests may be used to triage to follow-on RT-PCR tests (rather than all receiving PCR tests) dependent on prevalence and the consideration of the consequences of false positive and false negative results.

Where prevalence is low, *positive* rapid test results require confirmatory testing to avoid unnecessary quarantine measures (PPVs around 85% to 90% for antigen assays mean that between 1 in 10 and 1 in 7 positive results will be falsely positive). If unverified, negative rapid test results should be delivered with appropriate advice on self-isolation procedures for the duration of symptoms in order to minimise the effect on transmission of infection from missed cases. RT-PCR tests should still be considered for people with a high clinical suspicion of COVID-19 and negative rapid test.

Where prevalence is higher (i.e. 20% or higher), false positives are less of a concern (PPVs are 96% to 100%) but the impact from false negative results becomes increasingly important and all test *negatives* may be considered for verification. At 20% prevalence, and using data for the more sensitive of our three exemplar assays, between 3% and 6% of those with negative rapid test results are missed cases of SARS-CoV-2 (24 to 50 cases missed out of a total of 200 cases). The lower the NPV the greater the potential effect on transmission of infection from missed cases and greater the impact from delays in commencement of contact tracing. For scenarios in which positive results do not have confirmatory testing, it is important that assays with high specificities (in the range of 99% to 100%) are selected in order to minimise the impact from false positive results at higher prevalences of disease.

3. We identified virtually no evidence for mass screening of asymptomatic individuals using rapid antigen tests in people with no known exposure. A small study screening travellers returning from high-risk countries (Cerutti 2020), identified only five SARS-CoV-2 infections (prevalence of 3%) with a reported sensitivity of antigen testing for detecting infection of 40%. However, important larger studies have been published since the end of our search, as mentioned above.

The key focus in mass screening is identification of individuals who are or will become infectious. PCR-positives define those who had detectable viral particles on their swab, which will include most of those who are or will become infectious, but also include individuals post-infection with residual viral particles. Without a reference standard for infectiousness, test accuracy studies cannot assess the ability of the test to detect the infectious subgroup of infections, and cannot provide evidence as to how well rapid antigen tests differentiate between individuals requiring isolation and those who provide no risk. The effectiveness of mass screening using these tests will only be established though outcome studies, such as cluster-randomised community trials.

Given the low false positive rate of rapid tests, when used in a period of outbreak, those found testing positive will have a high chance of being true positives, and thus the test can be used to identify cases requiring isolation. Consideration should be made as to whether test positives should be confirmed with PCR to identify false positives. With a 1% prevalence, a test with 40% sensitivity and 99.6% specificity would yield as many false positives as true positives.

However, the low and variable sensitivity, and lack of evidence that those who test negative are not, or will not become, infectious

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review) Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

indicates that those who are rapid antigen test-negative cannot be considered free of risk of being, or of becoming, infectious. In any screening or mass testing programme people testing negative may still have a non-negligible risk of infection.

4. We did not find any evidence of test accuracy in at-risk asymptomatic groups, such as contacts of confirmed cases, hospital workers, or during local outbreaks at schools, workplaces, or care homes. The impact of low-sensitivity tests in these settings is greater than in mass screening, as there will be higher numbers of false negatives, which could either create new outbreaks or will increase the severity of existing outbreaks. Positive cases will be more likely to be true positives than in mass screening settings.

5. We did not find any evidence evaluating the repeated use of tests. Although serial testing (over a number of days), or combinations of different rapid tests (e.g. an antigen test followed by a rapid molecular test) on the same sample are proposed to overcome the limitations of low test sensitivity, they all require validation. Use of multiple tests may increase false positive results, and there are likely to be many individuals with repeated false negative results reducing the expected benefit of subsequent tests. It is unlikely that models will be able to predict how well repeated tests and test combinations would work.

6. Some rapid molecular tests showed promising accuracy levels approximating those of laboratory-based RT-PCR and thus may have a role in small-capacity settings where obtaining test results within two hours will enable appropriate decision making. Results for Xpert Xpress, COVID Nudge and SAMBA II all showed high sensitivity and specificity. However, we identified methodological concerns with many of the evaluations such that we cannot be certain as to how the tests will perform when used in a point-of-care setting. Any application in practice should be accompanied with a proper evaluation to ascertain performance in real-world settings. Rapid molecular tests do not have all the logistical advantage of rapid antigen tests and the resource implications of their use at scale are potentially high, but they may be well suited for some testing scenarios. There is no evidence for use of rapid molecular tests in asymptomatic populations.

Our conclusions are in line with those in the first version of this review despite the increase in the evidence base. Ultimately, decisions around rapid testing will be driven not only by diagnostic accuracy but by acceptable levels of test complexity, time to result, access and acceptability to those being tested, and how test results influence individual behaviour, all of which might vary according to the setting in which the tests are to be used.

Implications for research

There is now a considerable volume of research for point-of-care tests for SARS-CoV-2 infection. However further well designed prospective and comparative evaluations of individual tests and test strategies in clinically relevant settings are urgently needed. Studies should recruit consecutive series of eligible participants and should clearly describe the clinical status, document time from symptom onset or time since exposure. Point-of-care tests must be conducted in accordance with manufacturer instructions for use, and across the spectrum of point-of care settings and test operators. There needs to be evaluations of both individual tests and strategies of use of repeated tests. For molecular assays field trials are needed, not only to demonstrate test accuracy in these groups but acceptability and ease of use outside of centralised laboratories.

We observed a number of studies of molecular assays employing discrepant analysis to confirm the disease status of samples with false positive results in particular. There is a considerable risk of this type of selective re-testing leading to distorted results. If there is sufficient concern about the reliability of a single RT-PCR test then all samples should be tested with two RT-PCR assays. Finally, any future research study needs to be clear about eligibility and exclusion decisions throughout the whole diagnostic pathway, and should conform to the updated Standards for Reporting of Diagnostic Accuracy (STARD) guideline (Bossuyt 2015).

Consideration needs to be made of the best method for evaluating mass screening programmes. Whilst test accuracy studies help indicate which tests are likely to detect the greatest numbers of cases with the fewest false positives, assessing whether detecting asymptomatic cases leads to worthwhile reductions in disease spread will only be properly answered by studies of impact not accuracy.

ACKNOWLEDGEMENTS

Members of the Cochrane COVID-19 Diagnostic Test Accuracy Review Group include:

- the project team (Deeks JJ, Dinnes J, Takwoingi Y, Davenport C, Leeflang MMG, Spijker R, Hooft L, Van den Bruel A, McInnes MDF, Emperador D, Dittrich S, Cunningham J);
- the systematic review teams for each review:
 - * Molecular, antigen, and antibody tests (Adriano A, Arevalo-Rodriguez I, Beese S, Buitrago DC, Ciapponi A, Domen J, Dretzke J, Ferrante di Ruffano L, Harris I, Mateos M, Price M, Taylor M, Taylor-Phillips S)
 - * Signs and symptoms (Stuyf T, Domen J, Horn S)
 - * Routine laboratory markers (Yang B, Langendam M, Ochodo E, Guleid F, Holtman G, Verbakel J, Wang J, Stegeman I)
 - * Imaging tests (Salameh JP, McGrath TA, van der Pol CB, Frank RA, Prager R, Hare SS, Dennie C, Jenniskens K, Korevaar DA, Cohen JF, van de Wijgert J, Damen JAAG, Wang J);
- the wider team of systematic reviewers from the University of Birmingham, UK who assisted with title and abstract screening across the entire suite of reviews for the diagnosis of COVID-19 (Agarwal R, Baldwin S, Berhane S, Herd C, Kristunas C, Quinn L, Scholefield B).

The editorial process for this review was managed by Cochrane's Editorial and Methods Department Central Editorial Service in collaboration with Cochrane Infectious Diseases. We thank Helen Wakeford, Anne-Marie Stephani and Deirdre Walshe for their comments and editorial management. We thank Liz Bickerdike for comments on the Abstract. We thank Robin Featherstone and Douglas M Salzwedel for comments on the search and Mike Brown and Paul Garner for sign-off comments. We thank Denise Mitchell for her efforts in copy-editing this review.

Thank you also to peer referees Kristien Verdonck, David Sinclair and Jim Hugget, consumer referees Brian Duncan and Ceri Dare,

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Albert 2020

Study characteristics	
Patient Sampling	Single group study estimating sensitivity and specificity: Patients with clinical suspicion of COVID-19 (compatible signs or symptoms appearing within the prior week) attending one of 8 primary care centres (n=412)
	Recruitment: Not stated; likely consecutive
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Primary care
	Location: 8 primary care centres of the Health Department Clínico-Malvarrosa in Valencia.
	Country: Spain
	Dates: Sep 2nd to Oct 7 2020
	Symptoms and severity: All symptomatic (<7 days p.s.o)
	Demographics: median age, 31 y (range, 1-91); 42% male 327 adults; median, 36 y (17-91y) 85 children; median, 11 y (1-16y)
	Exposure history: Not stated
Index tests	Test name: Panbio™ COVID-19 AG Rapid Test Device (no product code report- ed)
	Manufacturer: Abbott Diagnostic GmbH, Jena, Germany
	Antibody: Nucleoprotein
	Antigen target: Not stated
	Test method: Not stated
	Samples used: NP; collected by trained nurses using flocked swabs
	Transport media: None for Ag testing
	Sample storage: None
	Test operator: Not stated; immediate testing

Albert 2020 (Continued)	Definition of test positivity: Visible line within 15 mins; As per manufacturer				
	Blinding reported: Yes				
	Timing of samples: Day <7 pso				
Target condition and reference standard(s)	Reference standard: RT-PCR; TaqPath COVID-19 Combo Kit (Thermo Fisher Sci- entific, Massachusetts, USA)				
	Definition of non-COVID cases: As for cases; single negative				
	Genetic target(s): ORF1ab, N and S genes				
	Samples used: NP in UTM				
	Timing of reference standard: As for index; tested within 24h				
	Blinded to index test: Not stated; presume Yes				
	Incorporated index test: No				
Flow and timing	Time interval between index and reference tests: Simultaneous; paired				
	All patients received same reference standard: Yes				
	Missing data: None reported; no participant flow diagram reported				
	Uninterpretable results: None reported				
	Indeterminate results (index test): None reported				
	Indeterminate results (reference standard): None reported				
	Unit of analysis: Patients				
Comparative					
Notes	Funding: This work received no public or private funds. Abbott Diagnostics provided Panbio™ COVID-19 AG Rapid Test Device kits.				
	Publication status: Pre-print				
	Source: medRxiv				
	Author COI: The authors declare no conflicts of interest				
Methodological quality					
Item	Authors' judgement Risk of bias Applicability concerns				
DOMAIN 1: Patient Selection					
Was a consecutive or random sample of patients enrolled?	Yes				
Was a case-control design avoided?	Yes				
Did the study avoid inappropriate exclusions?	Yes				
Did the study avoid inappropriate inclusions?	Yes				

Albert 2020 (Continued)			
Could the selection of patients have introduced bias?		Low risk	
Are there concerns that the included patients and setting do not match the review question?			Low concern
DOMAIN 2: Index Test (Antigen tests)			
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Could the conduct or interpretation of the index test have introduced bias?		Low risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			Unclear
DOMAIN 2: Index Test (Rapid molecular tests)			
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classi- fy the target condition?	No		
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference stan- dard?	Yes		
Were all patients included in the analysis?	Unclear		
Did all participants receive a reference standard?	Yes		
Were results presented per patient?	Yes		
Could the patient flow have introduced bias?		Unclear risk	

Alemany 2020

Study characteristics	
Patient Sampling	Single group study including particpants from three settings: [1] symptomatic individuals with suspected COVID-19 seen in routine practice (n=446) [2] contacts exposed to positive PCR confirmed COVID-19 cases (n=473) [3] preventive screening of unexposed asymptomatic individuals in the general popula- tion (n=487)
	Recruitment: Retrospective (frozen swabs)
	Prospective or retrospective: Not stated
Patient characteristics and setting	Setting: Mixed/Unclear (laboratory-based)
	Location: Not reported; multiple author institutions reported
	Country: Spain
	Dates: Not stated
	Symptoms and severity: Not stated; 15/1406 (1.1%) reportedly hospitalised (all PCR+) Viral load of cases: Ct <20: 258 (18.3%); Ct 20-24 305 (21.7%); Ct 25-29 285 (30.3%); Ct >30 103 (7.3%)
	Demographics: All samples: mean age 40.4y (SD 24.5), 453 (32.2% male)
	Exposure history: 473/1406 (33.6%) identified through contact tracing;
Index tests	Test name: Panbio TM COVID-19 Ag Test (no product codes) [Selected following valida- tion exercise using 40 NP samples to compare PanBio with Coris Bioconcept COVID-19 Ag RespiStrip, SD Biosensor Standard F COVID-19 Ag FIA and Standard Q COVID-19 Ag Test]
	Manufacturer: Abbott Laboratories, Illinois, USA
	Antibody: Not stated
	Antigen target: SARS-CoV-2
	Test method: CGIA
	Samples used: [1] and [2] NP, [3] nasal mid-turbinate; collection not reported
	Transport media: VTM (DeltaSwab Virus)
	Sample storage: stored at 2-8C prior to PCR then frozen (-80C) prior to Ag testing; "Internal validation showed no significant change in the test performance using Abbot test Kit buffer or a mix of the Kit buffer and transport media at 1:3 dilution; likewise, the use of frozen specimens showed no significant differences compared with fresh ones"
	Test operator: two laboratory technicians
	Definition of test positivity: Visible line; as per manufacturer
	Blinding reported: Yes
	Timing of samples: Not stated
Target condition and reference stan-	Reference standard: RT-PCR; in-house following CDC protocol
dard(s)	Definition of non-COVID cases: As per cases; single negative PCR for absence of infection
	Genetic target(s): Not stated; as per CDC protocol

Alemany 2020 (Continued)	Samples used: NP or nasal	mid-turbinate; as per ind	ex test
	Timing of reference standa RT-PCR	ard: fresh samples stored a	at 2 – 8 °C for up to 72 hours prior to
	Blinded to index test: Yes; o	conducted first	
	Incorporated index test: No	0	
Flow and timing	Time interval between ind	ex and reference tests: Sir	nultaneous (same swab)
	All patients received same	reference standard: Yes	
	Missing data: None reporte	ed; no participant flow dia	agram reported
	Uninterpretable results: No	one reported	
	Indeterminate results (ind	ex test): None reported	
	Indeterminate results (refe	erence standard): None re	ported
	Unit of analysis: Patients

Assennato 2020

Study characteristics	
Patient Sampling	Single-group study to estimate sensitivity and specificity: - samples from symptomatic individuals with suspected COVID-19 sent for routine labo- ratory diagnosis; supplied via PHE (n = 172)
	Recruitment: not stated
	Prospective or retrospective: retrospective
	Number of samples (samples with confirmed SARS-CoV-2): 172 (88)
Patient characteristics and setting	Setting: not stated; supplied by PHE
	Location: PHE, Cambridge Laboratory (samples from East of England)
	Country: UK
	Dates: not stated
	Symptoms and severity: symptomatic; no further details
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: SAMBA II SARS-CoV-2 Test
	Manufacturer: Diagnostics for the Real World
	Antigen target: ORF1ab, N2
	Antibody: N/A
	Test method: rapid PCR
	Samples used: combined nose and throat swab samples, provided as VTM
	Transport media: samples diluted 1:2 with SAMBA SCoV buffer
	Sample storage: not stated
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: as per manufacturer; either target present
	Blinding reported: yes; states that samples were rendered anonymous and provided blinded for the purpose of test validation
	Timing of samples: not stated
Target condition and reference stan- dard(s)	Reference standard: RT-PCR; (1) Cambridge RdRp gene (Wuhan) assay on the Rotor gene Q real-time PCR assay routinely used by PHE; Ct ≤ 36 considered positive. (2) Samples al- so tested with the PHE Colindale (Reference Laboratory) assay
	Definition of non-COVID cases: Single RT-PCR negative
	Genetic target(s): (1) RdRp, E gene, (2) RdRp 'different region'
	Samples used: combined nose and throat swab in VTM; same as for index test
	Timing of reference standard: not stated; Cambridge assay seems to have been part of routine testing near to time of sample collection; not clear if Colindale assay was at a later date after a period of storage

_

Trusted evidence. Informed decisions. Better health.

iillaud 2020	
Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity:
	- teachers (n=90) and students (n=419) screened for COVID-19 as part of a cluster investigation (n=509)
	Recruitment: Not stated; appears to be open to all
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Screening
	Location: College, Lyon
	Country: France
	Dates: September 16 and 17
	Symptoms and severity: 166/509, 32.6% symptomatic including 152/419 (36%) students
	Demographics: Mean, median age Students 21.6y, 21y (18 to 37y) Teachers 47.2y, 49y (26 to 64y)
	Exposure history: Outbreak investigation
Index tests	Test name: Described as "ABBOTT SARS-COV2 Antigenic Test"; presumed to be Panbio COVID-19 Ag Test
	Manufacturer: Abbott
	Antibody: Not stated
	Antigen target: Not stated
	Test method: Not stated
	Samples used: NP; collected by firefighters
	Transport media: None used
	Sample storage: n/a; tested immediately on site
	Test operator: Not stated
	Definition of test positivity: Visual line; as per manufacturer
	Blinding reported: Yes, performed first
	Timing of samples: Not stated but includes people >7 days pso
Target condition and reference standard(s)	Reference standard: RT-PCR; SARS-COV-2 (Thermofisher)
	Definition of non-COVID cases: As for cases; single negative
	Genetic target(s): Not stated
	Samples used: NP (paired)
	Timing of reference standard: As for index
	Blinded to index test: Not stated

-low and timing	Time interval between i	index and reference to	ests: Simultaneous

Could the patient flow have introduced bias?		High risk	

Blairon 2020

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity: sampled from cohort of sus- pected COVID-19 patient samples sent for laboratory diagnosis (n=56) [Excluded data for full cohort, as only those with negative antigen test underwent con firmatory RT-PCR; of 912 submitted samples during time period, 776 remained after re moving repeat tests and were reported in main study] Recruitment: Selection of 56 for verification analysis was not reported.
	Prospective or retrospective: prospectively
Patient characteristics and setting	Setting: Unclear; swabs obtained at hospital site (no further detail)
	Location: Not stated; author institution Iris Hospitals South, Brussels
	Country: Belgium
	Dates: April 5 - May 4 2020
	Dates. April 5 - May 4 2020

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review)

Copyright © 2021 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.

Slairon 2020 (Continued)	
	Symptoms and severity: Not stated
	Demographics: Not stated
	Exposure history: Not stated
Index tests	Test name: COVID-19 Ag Respi-Strip (no product code reported)
	Manufacturer: Coris Bioconcept (Gembloux, Belgium)
	Antibody: Not stated
	Antigen target: Not stated
	Test method: LFA
	Samples used: NP swabs; collection not reported
	Transport media: Samples for antigen testing taken from UTM-RT swabs (Copan spa, Brescia, IT)
	Sample storage: No storage described; infer that antigen test was conducted immediately on receipt of sample at on-site laboratory 'after antigenic testing was performed the molecular assessment of SARS-CoV-2 was outsourced to a university centre'
	Test operator: Not stated; infer laboratory staff
	Definition of test positivity: As per manufacturer
	Blinding reported: Not stated; infer yes as conducted prior to PCR confirmation
	Timing of samples: Not stated; appears to be on presentation (repeat tests ordered at clinician's discretion were excluded)
Target condition and reference standard(s)	Reference standard: qRT-PCR
	Definition of non-COVID cases: As above, single PCR negative to confirm absence of disease
	Genetic target(s): E gene
	Samples used: NP swabs (same as for Ag test)
	Timing of reference standard: Not stated
	Blinded to index test: Not stated
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Not stated but infer short interval; samples sent to university centre laboratory for PCR confirmation
	All patients received same reference standard: Yes (only if author confirms Ag+ also g PCR)
	Missing data: None reported; review team excluded main cohort data as no reference standard for antigen test positive samples
	Uninterpretable results: None reported; 1 'invalid' sample excluded from main cohor
	Indeterminate results (index test): None reported; 1 'non-conform' sample excluded from main cohort
	Indeterminate results (reference standard): None reported

Blairon 2020 (Continued)

Unit of analysis: Unclear; main cohort includes unique patient samples but not reported for separate group of 56

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	No		
Was a case-control design avoided?	No		
Did the study avoid inappropriate exclusions?	Unclear		
Did the study avoid inappropriate inclusions?	Unclear		
Could the selection of patients have introduced bias?		High risk	
Are there concerns that the included patients and setting do not match the review question?			High
DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecular tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Unclear		
If a threshold was used, was it pre-specified?	Yes		
Could the conduct or interpretation of the in- dex test have introduced bias?		Unclear risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			Unclear
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly clas- sify the target condition?	Yes		
Were the reference standard results interpret- ed without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		

Broder 2020 (Continued)

Trusted evidence. Informed decisions. Better health.

Could the reference standard, its conduct, or its interpretation have introduced bias?		Unclear risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference stan- dard?	Yes		
Were all patients included in the analysis?	Unclear		
Did all participants receive a reference standard?	Yes		
Were results presented per patient?	Unclear		
Could the patient flow have introduced bias?		Unclear risk	

Cerutti 2020

Single group study to estimate sensitivity and specificity in two cohorts: (1) symptomatic patients attending one of two Emergency departments (n=185) (2) asymptomatic travellers returning home from European high risk countries (Croatia, Spain, Malta) (n=145)
Recruitment: (1) Random; (2) Not stated, presume consecutive
Prospective or retrospective: Not stated
Setting: Mixed; (1) Emergency department; (2) Possible contacts
Location: (1) two Infectious Disease reference centres in North-Italy (ASL Citt`a di Torino, Turin and San Martino University Hospital, Genoa); (2) Not stated; samples sent to Microbiology and Virology Laboratory, Amedeo di Savoia Hospital, Torino
Country: Italy
Dates: (1) Mar 3 to May 1; (2) August 2020
Symptoms and severity: Not stated; cohort (2) were asymptomatic
Demographics: (1) mean age 44.6, 95 %CI: 40.7–48.6; (2) mean age 35.9, 95 % CI: 32.7–39.1
Exposure history: (1) Not stated; (2) High risk country visit
Test name: STANDARD Q COVID-19 Ag
Manufacturer: SD-Biosensor, RELAB, I
Antibody: NP

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review)

Could the patient flow have introduced bias?		Unclear risk

Chen 2020a

Study characteristics	
Patient Sampling	Single group study using: - archived paired samples from COVID-19 inpatients (n=58). Aim is to compare diagnos- tic yield between saliva and NP swabs but can also extract sensitivity for each using rapid test.
	Recruitment: Not stated
	Prospective or retrospective: Retrospective
Patient characteristics and setting	Setting: In-patients
	Location: Queen Mary Hospital, Pokfulam, Hong Kong
	Country: People's Republic of China
	Dates: Not stated
	Symptoms and severity: Not stated
	Demographics: Median age 38 y; 28, 48% male
	Exposure history: Not stated
Index tests	Test name: Xpert Xpress SARS-CoV-2 assay (no product codes reported)
	Manufacturer: Cepheid, Sunnyvale, CA, USA
	Target gene(s): E and N2 gene
	Antigen target: n/a
	Test method: Automated RT-PCR
	Samples used: NP, saliva (posterior oropharyngeal, self-collected by clearing the throat and spitting c1 mL saliva directly into a sterile bottle in the early morning before mouth rinsing and breakfast)
	Transport media: Both sample types immersed in 2ml of viral transport solution
	Sample storage: Not stated; archived

Item	Authors' judgement Risk of bias Applicability concerns

Did all participants receive a reference standard?	Yes
Were results presented per patient?	Yes
Could the patient flow have introduced bias?	Unclear risk

Collier 2020

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity: suspected COVID-19 patients admit- ted with a possible diagnosis of COVID-19 (n=149)
	Recruitment: Consecutive
	Prospective or retrospective: prospectively
Patient characteristics and setting	Setting: In-patients
	Location: Cambridge University Hospitals NHS Foundation Trust
	Country: UK
	Dates: April 6 - May 2 2020
	Symptoms and severity: Not stated
	Demographics: Mean age 62.7 y, 70, 47% male
	Exposure history: Not stated
Index tests	Test name: SAMBA II SARS-CoV-2 test (no product code reported)
	Manufacturer: Diagnostics for the Real World (DRW), University of Cambridge, Cambridge
	Target gene(s): Orf1 and the E genes
	Antigen target: n/a
	Test method: RT-PCR
	Samples used: combined nasal/throat swab (NOP) on dry sterile swab. Collection not reported
	Transport media: None used; samples inactivated in SCov buffer prior to testing
	Sample storage: Not stated. Test performed within 18 hours of reference test
	Test operator: Not stated; infer laboratory staff
	view based tests for diagnosis of SARS CoV 2 infection (Paviau)

Collier 2020 (Continued)				
	Definition of test positivity: As per manufacturer			
	Blinding reported: Unclear; yes if always conducted before reference test but not explicitly de- scribed, i.e. 'SAMBA swab must be taken within 18 hours of the standard laboratory swab'			
	Timing of samples: Not stated; appears to be on presentation/admission but no further details			
Target condition and reference	Reference standard: RT-PCR; in-house PHE assay			
standard(s)	Definition of non-COVID cases: As above, single PCR negative to confirm absence of disease			
	Genetic target(s): Not stated			
	Samples used: Not stated; separate swab used as participants were excluded if >18h interval between swab collections			
	Timing of reference standard: Not stated			
	Blinded to index test: Yes; 'The results of the SAMBA II SARS-CoV-2 was not known to the asses- sors of the standard lab RT-PCR prior.' Not stated. Possibly if done prior to index test.			
	Incorporated index test: No			
Flow and timing	Time interval between index and reference tests: <18 hours			
	All patients received same reference standard: Yes			
	Missing data: Yes; 5 discarded VTM, 1 timing of PHE swab not reported, 1 inadequate SAMBA swab, 2 interval between swabs >24h			
	Uninterpretable results: None reported			
	Indeterminate results (index test): Not stated 'Indeterminate SAMBA II SARS CoV-2 tests were repeated with a 1:2 dilution of sample to inacti- vation buffer according to manufacturer standard operating procedures until a valid result was obtained.' Discrepant results between index and reference were also re-tested using SAMBA-II on original samples			
	Indeterminate results (reference standard): 1 false negative Indeterminate standard lab RT PCR tests were repeated on a replicate nose/throat swab until a valid result was obtained. Discrepant results between index and reference were re-tested using RT-PCR on original sam- ples, with reference to clinical notes to determine clinical suspicion. Remaining discrepant re- sults were re-tested using alternative sample, i.e. sample in SCov buffer tested on RT-PCR and sample in VTM tested on SAMBA-II

DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecular tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Unclear		
If a threshold was used, was it pre-specified?	Yes		
Could the conduct or interpretation of the in- dex test have introduced bias?		Unclear risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			Unclear
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly clas- sify the target condition?	No		
Were the reference standard results interpret- ed without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		

Cradic 2020(b) (Continued)		
Did all patients receive the same reference stan- dard?	Yes	
Were all patients included in the analysis?	Unclear	
Did all participants receive a reference standard?	Yes	
Were results presented per patient?	Yes	
Could the patient flow have introduced bias?		Unclear risk

Diao 2020

Study characteristics	
Patient Sampling	Single group estimating sensitivity and specificity for detecting active disease - samples from cases of suspected SARS-CoV-2 infection (n = 239)
	Recruitment: not stated if participants were consecutive
	Prospective or retrospective: retrospective
	Number of samples (samples with confirmed SARS-CoV-2): 239 (208)
Patient characteristics and setting	Setting: hospital (inpatients)
	Location: 7 centres, including General Hospital of Central Theatre Command, Wuhan No.7 People's Hospital, Wuhan Pulmonary Hospital, Hubei Maternal and Child Hos- pital, Taikang Hospital, Hanyang Hospital and Wuguo Hospital. Urine study done in Southwest Hospital in Chongqing
	Country: China
	Dates: not stated
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: not stated
	Manufacturer: in house (but study authors affiliated to Bioeasy Technology)
	Antibody: monoclonal antibody
	Antigen target: nucleocapsid protein (N-antigen)
	Test method: FIA (fluorescence immunochromatographic); requires immunofluores- cence analyser
	Samples used: NP (all), urine (subgroup)
	Transport media: samples diluted and mixed in 500 μL saline solution; 100 μL transferred to the sample well of the test card
	Sample storage: not reported
	Test operator: not stated; presume laboratory staff

Diao 2020 (Continued)	Definition of test positivity: cut-off value was determined by testing 100 nasal swab samples of healthy people and calculated as the mean value of the fluorescence signa plus 5 SD.		
	Blinding reported: done in parallel; blinded		
	Timing of samples: not stated		
Target condition and reference standard(s)	Reference standard: RT-PCR (Daan Gene kit); performed on ABI Prism 7500 and Light Cycler 480 real-time PCR system. Threshold < 40 Ct; threshold < 30 Ct also investigated Definition of non-COVID cases: all participants underwent 3 nucleic acid tests, and the results of each nucleic acid test were verified by 2 COVID-19 nucleic acid test kits.		
	Genetic target(s): ORF1ab and N gene		
	Samples used: NP swab, same as for index test		
	Timing of reference standard: not stated		
	Blinded to index test: done in parallel; blinded		
	Incorporated index test: no		
Flow and timing	Time interval between index and reference tests: done in parallel		
	All participants received same reference standard: yes		
	Missing data: not reported, no participant flow diagram reported		
	Uninterpretable results: not reported		
	Indeterminate results (index test): none reported		
	Indeterminate results (reference standard): none described		
	Unit of analysis: participants		
Comparative

FIND 2020a

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity: - patients with symptoms consistent with COVID-19 (meeting national definition for testing) presenting at a community testing clinic
	Recruitment: Consecutive recruitment
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Community (COVID-19 testing clinic)
	Location: Institution not described; Marica, Rio de Janeiro
	Country: Brazil
	Dates: 30 Jul to 21 Aug 2020
	Symptoms and severity: All symptomatic; no further details
	Demographics: mean age 40y (range 4 to 84); reported for 396 participants 181 (45%) male
	Exposure history: Not stated
Index tests	Test name: NowCheck COVID-19 Ag test (RG1901DG)

FIND 2020a (Continued)	
	Manufacturer: Bionote Inc
	Antibody: SARS-CoV-2 nucleocapsid antigen
	Antigen target: Mouse monoclonal SARS-CoV-2 antibodies
	Test method: Rapid chromatographic immunoassay in lateral flow format
	Samples used: Proprietary NP swab collected by HCW
	Transport media: No transport media. Sample is immediately transferred to proprietary tube containing extraction buffer.
	Sample storage: Test should be performed as soon as possible after collection. Specimens may be stored at RT for 1h or 2-8°C for 4h.
	Test operator: HCW
	Definition of test positivity: Presence of visible control and test lines
	Blinding reported: Yes
	Timing of samples: median 4 days p.s.o (IQR 3, 6 days); day <0 to 3 152, 39% day 4 to 7 180, 46% day >=8 58, 15%
Target condition and reference standard(s)	Reference standard: RT-PCR (in-house assay based on the US CDC protocol); Ct threshold of 37
	Definition of non-COVID cases: Same as for cases. Single negative PCR required for absence of infection
	Genetic target(s): N1, N2
	Samples used: NP swabs
	Timing of reference standard: Same timing as per NP swabs for index test
	Blinded to index test: Yes
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: 0 to several days based on PCR turnaround times at the lab
	All patients received same reference standard: Yes
	Missing data: Reports 0 invalid results
	Uninterpretable results: None reported
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported

Methodological quality				
ltem	Authors' judgement	Risk of bias	Applicability concerns	
DOMAIN 1: Patient Selection				
Was a consecutive or random sample of pa- tients enrolled?	Yes			
Was a case-control design avoided?	Yes			
Did the study avoid inappropriate exclusions?	Yes			
Did the study avoid inappropriate inclusions?	Yes			
Could the selection of patients have intro- duced bias?		Low risk		
Are there concerns that the included pa- tients and setting do not match the review question?			Low concern	

FIND 2020c (BR) (Continued)			
DOMAIN 2: Index Test (Antigen tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Could the conduct or interpretation of the index test have introduced bias?		Low risk	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?			Low concern
DOMAIN 2: Index Test (Rapid molecular tests)			
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly classify the target condition?	No		
Were the reference standard results interpret- ed without knowledge of the results of the in- dex tests?	Yes		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between in- dex test and reference standard?	Yes		
Did all patients receive the same reference standard?	Yes		
Were all patients included in the analysis?	Yes		
Did all participants receive a reference stan- dard?	Yes		
Were results presented per patient?	Yes		
Could the patient flow have introduced bias?		Low risk	

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity at single site; this extrac- tion is for data from Switzerland (see FIND 2020c (BR) and Kruger 2020(c) for ex- traction of data from other sites): - patients seeking COVID-19 testing at main testing centre; described as present- ing either with symptoms compatible with a SARS-CoV2 infection, or with a known positive contact or asymptomatic HCWs (n=529; from total cohort of 1064 volun- teers)
	Recruitment: Consecutive recruitment
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Community (main testing centre)
	Location: Hopitaux Universitaires de Geneve (HUG), Geneva
	Country: Switzerland
	Dates: 9-23 Oct 2020
	Symptoms and severity: Not stated; time pso recorded for 183/191, 96% 141/183 COVID positive cases had symptoms for 0-4days (77%)
	Demographics: Not stated
	Exposure history: Not stated
Index tests	Test name: STANDARD Q COVID-19 Ag (09COV30D)
	Manufacturer: SD Biosensor Inc
	Antibody: Not reported
	Antigen target: Not reported
	Test method: Rapid chromatographic immunoassay in lateral flow format
	Samples used: NP
	Transport media: Proprietary swab/media provided by SD Biosensor
	Sample storage: Author contact advises tested as soon as possible and within the time limit specified in the IFU
	Test operator: HCW
	Definition of test positivity: Presence of visible control and test lines
	Blinding reported: Yes
	Timing of samples: median not reported (range 0 to 15); day <0 to 3 - 122, 67%; da 4-7 - 54, 29%; Day 8+ - 7, 34%
Target condition and reference standard(s)	Reference standard: RT-PCR Roche Cobas; Ct threshold <40 (from Figure)
	Definition of non-COVID cases: Same as for cases. Single negative PCR required fo absence of infection
	Genetic target(s): Not stated
	Samples used: NP swab (paired, from contralateral nostril)

FIND 2020c (CH) (Continued)	Timing of reference stand swabs used.	ard: Not stated; author cont	act advises only paired
	Blinded to index test: Yes

	 [A] SARS-CoV-2 COVID-19 Respi-Strip [B] Standard Q COVID-19 Ag [C] PanBio COVID-19 Antigen Rapid Test [D] Biosynex COVID-19 Ag BSS [E] COVID-VIRO Antigen Rapid Test [F] NG Test SARS-CoV-2 Ag (assay excluded from review due to Vortex requirement as stated in IFU) (no product codes reported)
	Manufacturer:
	[A] Coris BioConcept, Gembloux, Belgium [B] SD BIOSENSOR, Inc., Korea [C] Abbott, Chicago, Illinois, USA [D] Biosynex, Strasbourg, France [E] AAZ, Boulogne-Billancourt, France [F] NG Biotech, Guipry, France
	Antibody: Not stated
	Antigen target: Not stated
	Test method: Not stated
	Samples used: NP; collection not reported
	Transport media: VTM (Cepheid® or Deltalab®); 100 μ L used for testing
	Sample storage: frozen at -80 °C until use
	Test operator: Laboratory staff
	Definition of test positivity: Visual, as per manufacturer.
	Blinding reported: Yes; each test was interpreted independently by two different laborato- ry technicians. A third reading was carried out in the event of discrepancy
	Timing of samples: post-symptom onset (reported for 289 samples): 0-3 days 97, 34%; 4-7 days 103, 36%; 8=11 days 63, 22%; >=12 days 26, 9% No. samples reported at >7 days varied per test, maximum was 289
Target condition and reference stan- dard(s)	Reference standard: RT-PCR; in-house assay developed by CNR (Institut Paster) or RealStar SARS-CoV-2 (Altona Diagnostics, Germany)
	Definition of non-COVID cases: Pre-pandemic
	Genetic target(s): Not stated
	Samples used: NP; same as for index
	Timing of reference standard: As for index
	Blinded to index test: Yes, seems to be at time of sampling
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Same swab; simultaneous
	All patients received same reference standard: Yes
	Missing data: Number of cases missing per assay varied; reasons for missing data not re- ported (presumably invalid assay results)

Notes			
Ghofrani 2020			
Study characteristics			
Patient Sampling	Single group study to estimate sensitivity and specificity in patients with both RT- PCR and POCT results available (n=113), including: [1] symptomatic patients with a PCR swab test close to presentation and a re-swab for POC testing, [2] patients with positive RT-PCR results and remnant NP swabs available for POC test, [3] asymptomatic patients with positive POC result on admission who were re- swabbed for RT-PCR confirmation. N per group was not reported		
	Recruitment: Convenience		
	Prospective or retrospective: Retrospective		
Patient characteristics and	d setting Setting: Unclear; primarily in-patients?		
	Location: PeaceHealth Medical Group (10 hospitals and numerous clinics serving suburban and rural communities in three states)		
	Country: USA		
	Dates: April 6- April 21 2020		
	Symptoms and severity: Majority' symptomatic, no further details.		
	Demographics: Not stated		
	Exposure history: Not stated		
Index tests	Test name: ID NOW COVID-19 assay (no product code reported)		
	Manufacturer: Abbott Laboratories		
	Target gene(s): RdRp region		
	Antigen target: n/a		
	Test method: Isothermal PCR		
	Samples used: Nasal 58 (51.3%), NP 33 (29.2%), not stated 22 (19.5%). Direct testing 58 (51.3%), UTM 26 (23.0%); not stated 29 (25.7%).		
	Transport media: None or UTM; no further details		
	Sample storage: Not stated		
	Test operator: Not stated; infer laboratory staff.		
	Definition of test positivity: Not stated; presume as per manufacturer

High risk

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity with three sources of participants: [1] self-referred, health-care workers or their family members with suspected COVID-19 who were not admitted to hospital (n=280) [2] emergency department patients with suspected COVID-19 (n=15) [3] hospital inpatient admissions with or without suspected COVID-19 (n=91) Total N was 418 paired samples; 32 excluded as invalid (patient group not reported), 24 invalid on DnaNudge and 8 on RT-PCR)
	Recruitment: [1] and [2] Not reported; [3] consecutive
	Prospective or retrospective: Prospective
Patient characteristics and	Setting: Mixed ([1] community, [2] A&E, [3] Inpatient)
setting	Location: [1] St Mary's Hospital and the John Radcliffe Hospital, [2] St Mary's Hospital, [3] Chelsea & Westminster Hospital
	Country: London or Oxford, UK
	Dates: [1] April 10 to May 12, [2] April 2 to 24, [3] May 12 to 18
	Symptoms and severity: Only group [3] were inpatient
	Demographics: median age 46 y (IQR 31–66); 124, 32% male
	Exposure history: Not reported
Index tests	Test name: CovidNudge (no product code)
	Manufacturer: DnaNudge, UK
	Antibody: rdrp1, rdrp2, e-gene, n-gene, n1, n2, and n3
	Antigen target: n/a
	Test method: Automated RT-PCR; Described as "integrated lab-on-chip device that enables sam- ple-to-result (RT-)PCR"
	Samples used: NP; HCW obtained swabs using pediatric swab
	Transport media: None
	Sample storage: No delay reported
	Test operator: Unclear; possibly HCW
	Definition of test positivity: at least two replicates of at least one viral gene target amplified
	Blinding reported: Yes; results from CovidNudge testing reported before laboratory results were available
	Timing of samples: On presentation; timing not reported

Gibani 2020 (Continued)	
Target condition and refer- ence standard(s)	Reference standard: SARS-CoV-2 RT-PCR; assay varied by site. A. AusDiagnostics MT-PCR (Orf1ab, Orf8); n=74 b. Roche RT-PCR (Orf1ab, E); N=81 c. Abbott RT-PCR (RdRp, N); n=66 d. ThermoFisher (orf1ab, the spike (S) gene and the nucleocapsid (N) gene); n=21 e. PHE in-house RT-PCR (RdRp); n=120 f. Imperial Molecular Diagnostics Unit (E); n=24
	Definition of non-COVID cases: As above (single negative)
	Genetic target(s): See above
	Samples used: NOP (paired)
	Timing of reference standard: Not stated
	Blinded to index test: Yes; centralised laboratory testing and point-of-care testing were done by separate staff members. Staff doing the centralised laboratory testing were masked to the point of-care test results and vice-versa
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Simultaneous (paired)
	All patients received same reference standard: Yes (different assays)
	Missing data: Additional 47 samples not 'paired'; not collected on same date
	Uninterpretable results: 32 samples excluded; 24 invalid on DNANudge (failed to amplify RNaseP; 22/24 with associated RT-PCR result were negative) and 8 on RT-PCR (all 8 from one site)
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported
	Unit of analysis: Patients

Was there an appropriate in- terval between index test and reference standard?	Yes				
Did all patients receive the same reference standard?	Yes				
Were all patients included in the analysis?	No				
Did all participants receive a reference standard?	Yes				
Were results presented per pa- tient?	Yes				
Could the patient flow have introduced bias?		Hig	h risk		

Goldenberger 2020

Study characteristics	
Patient Sampling	 Design unclear but appears to be a two group study to estimate sensitivity and specificity: [1] SARS-CoV-2 positive samples selected to reflect a broad range of Ct values (n=10) [2] SARS-CoV-2 negative samples (n=9) Groups [1] and [2] from patients suspected of COVID-19 undergoing routine diagnostics within a one week period [third cohort of pre-pandemic samples positive for other coronaviruses reported but not included in review (n=8)] Recruitment: Convenience Prospective or retrospective: Unclear
Patient characteristics and setting	Setting: Unclear
	Location: University Hospital Basel

Goldenberger 2020 (Continued)	
	Country: Switzerland
	Dates: One week during 2020 pandemic
	Symptoms and severity: Not reported
	Demographics: Not reported
	Exposure history: Not reported
Index tests	Test name: Xpert Xpress (no product code)
	Manufacturer: Cepheid Inc
	Antibody: E, N2
	Antigen target: n/a
	Test method: Automated RT-PCR
	Samples used: NP
	Transport media: UTM or eSwab media (Copan)
	Sample storage: frozen at −80 °C until batch-wise sample processing with the Xpert
	Test operator: laboratory technician
	Definition of test positivity: Not stated; both targets reported in all samples
	Blinding reported: Unclear
	Timing of samples: Not stated
Target condition and reference standard(s)	Reference standard: Roche cobas RT-PCR; threshold not reported but all posi- tive samples <33 Ct
	Definition of non-COVID cases: [2] COVID-19 suspects; as for cases (single negative PCR)
	Genetic target(s): E, ORF1
	Samples used: NP (same as index)
	Timing of reference standard: Not stated
	Blinded to index test: Yes, conducted first
	Incorporated index test: Not stated
Flow and timing	Time interval between index and reference tests: Simultaneous (same swab)
	All patients received same reference standard: Yes
	Missing data: None reported, no participant flow diagram reported
	Uninterpretable results: None reported
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported

Goldenberger 2020 (Continued)			
Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk		
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference stan- dard?	Yes		
Were all patients included in the analysis?	Unclear		
Did all participants receive a reference standard?	Yes		
Were results presented per patient?	Unclear		
Could the patient flow have introduced bias?		Unclear risk	

Gremmels 2020(a)

Study characteristics	
Patient Sampling	Report of two cohorts of patients presenting for COVID-19 testing. Gremmels 2020(a) en- try relates to: [1] community-dwelling mildly symptomatic subjects in a medium endemic area (n=1369)
	Gremmels 2020(b) entry reports data for second cohort in a high endemic area
	Recruitment: Yes; all individuals invited to participate
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Community testing centre
	Location: [1] University Medical Center Utrecht (UMCU)
	Country: Netherlands
	Dates: [1] Sep 22 to Oct 6
	Symptoms and severity: Cohort [1] only. Data on symptoms were missing from nine subjects Asymptomatic 37, 2.7%, Sore throat 907, 66.3%; Coryza 943, 69%; Cough 780, 57.1%; Headache 601, 44.0%; Tiredness 565, 41.3%; General malaise 365, 26.7% (further 19 doc- umented)
	Demographics: median age 36.4y (IQR 27.0, 49.6y); 523, 38.3% male
	Exposure history: 233, 17% contact with confirmed case
Index tests	Test name: Panbio™ COVID-19 Ag Rapid Test (lot 41ADF011A)

.

Trusted evidence. Informed decisions. Better health.

Gremmels 2020(a) (Continued)	Manufacturer: Abbott (Lake Country, IL, U.S.A)
	Antibody: NP
	Antigen target: Not stated
	Test method: Not stated
	Samples used: NP; obtained after NOP swab for RT-PCR; implies collected by HCW
	Transport media: Unclear; states transferred to 3 ml UTM after collection until further processing but also describes collected swabs transferred into dedicated sample collec- tion tubes containing a sampling buffer for Ag test
	Sample storage: Not stated; within 2 hours of collection
	Test operator: Two independent observers
	Definition of test positivity: Visual line within 15 mins; as per manufacturer
	Blinding reported: Yes; observers (blinded to each other and to the PCR results)
	Timing of samples: Cohort [1] (data on duration of symptoms reportedly missing for 201 subjects; total reported here is 1138 but denominator for %s is 1166) day 1-3 pso 387, 33.2%; day 4-7 560, 48.0%; day >7 191, 16.4%
Target condition and reference stan- dard(s)	Reference standard: RT-PCR; Seegene Allplex positive result on amplification of any of the three SARS-CoV-2 genes
	Definition of non-COVID cases: As for cases; single negative result
	Genetic target(s): E-, N-, and RdRP-gene
	Samples used: NOP (paired)
	Timing of reference standard: NOP swab obtained first for RT-PCR
	Blinded to index test: Not stated
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Paired
	All patients received same reference standard: Yes
	Missing data: 2 patients excluded ('inappropriate application of NP swab and lab misla- belling'), disease status not reported. [Considered overall low risk of bias due to small numbers]
	Uninterpretable results: None reported
	Indeterminate results (index test): None; no bands were classified as unclear by the in- dependent observers
	Indeterminate results (reference standard): Patients
	Unit of analysis:
Comparative	
Notes	Funding: This study was investigator initiated. No external funding was received
	Publication status: Pre-print
	Source: medRxiv

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Yes		
Was a case-control design avoided?	Yes		
Did the study avoid inappropriate exclusions?	Yes		
Did the study avoid inappropriate inclusions?	Yes		
Could the selection of patients have introduced bias?		Low risk	
Are there concerns that the included patients and setting do not match the review question?			Low concern
DOMAIN 2: Index Test (Antigen tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Yes		
If a threshold was used, was it pre-specified?	Yes		
Could the conduct or interpretation of the in- dex test have introduced bias?		Low risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			High
DOMAIN 2: Index Test (Rapid molecular tests)			
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly clas- sify the target condition?	No		
Were the reference standard results interpret- ed without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			

Gremmels 2020(b) (Continued)		
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference stan- dard?	Yes	
Were all patients included in the analysis?	Yes	
Did all participants receive a reference standard?	Yes	
Were results presented per patient?	Yes	
Could the patient flow have introduced bias?		Low risk

Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity: - symptomatic patients with suspected COVID-19 and asymptomatic contacts of laboratory-confirmed cases between 5 and 10 days of exposure, meeting Indian Council of Medical Research (ICMR) strategy for COVID-19 testing Recruitment: Consecutive
	Prospective or retrospective: Not stated; appears prospective
Patient characteristics and setting	Setting: Outpatient (tertiary care hospital)
	Location: All India Institute of Medical Sciences (AIIMS), New Delhi
	Country: India
	Dates: May 31 to July 24, 2020.
	Symptoms and severity: 204 (62%) symptomatic; 126 (38%) asymptomatic. median symptom duration: 1 day (range: 1-10). Symptoms included: fever (31.5%), cough (25.4%), fatigue/malaise (11.8%), headache (3.3%), runny nose (3.3%)
	Demographics: median age 34.1±12.6 yr; 231 (70%) male
	Exposure history: 127 asymptomatic were in contact with confirmed case
Index tests	Test name: Standard Q rapid antigen detection test
	Manufacturer: SD Biosensor, Inc., Gurugram
	Antibody: Not stated
	Antigen target: Not stated
	Test method: Not stated
	Samples used: NP; collection method detailed but personnel not described; pre- sume HCW. Sequence for specimen collection was random for both the samples (Ag and RT-PCR)
	Transport media: None
	Sample storage: None

upta 2020 (Continued)			
	Test operator: Same person who obtained swab; HCW		
	Definition of test positivity: Visual; test and control lines		
	Blinding reported: Yes; conducted first		
	Timing of samples: Symptomatic: 192 (95%) <=5 days pso (incl 57 cases)		
Target condition and reference standard(s)	Reference standard: RT-PCR; commercial assay (BGI Genomics Co. Ltd., China). Psoitive defined as per manufacturer IFU		
	Definition of non-COVID cases: As for cases; single negative		
	Genetic target(s): ORF1 ab		
	Samples used: nasal and throat swabs (NOP) in VTM		
	Timing of reference standard: As for index test; states the sequence for specimen collection was random for both the samples		
	Blinded to index test: Not stated		
	Incorporated index test: No		
Flow and timing	Time interval between index and reference tests: Simultaneous; paired swabs		
	All patients received same reference standard: Yes		
	Missing data: None reported, no participant flow diagram reported

Study characteristics	
Patient Sampling	Single-group study to estimate sensitivity and specificity: - symptomatic patients meeting diagnostic criteria for COVID-19 (n = 524)
	Recruitment: consecutive
	Prospective or retrospective: unclear; presume prospective
	Number of samples (samples with confirmed SARS-CoV-2): 524 (186)
Patient characteristics and setting	Setting: ED (n = 3) or urgent (immediate) care centres (n = 2)
	Location: not stated; author institutions Loyola University Medical Centre, Cedars-Si- nai Medical Centre
	Country: USA
	Dates: not reported
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
ndex tests	Test name: ID NOW COVID-19 assay (no product code provided)
	Manufacturer: Abbott
	Antigen target: not stated
	Antibody: N/A
	Test method: not stated; isothermal PCR
	Samples used: nasal swabs (provider collected)
	Transport media: none; direct testing after heat inactivation
	Sample storage: ED swabs transported in sterile transport containers (using cups or conical tubes)
	Test operator: on-site medical personnel (urgent care centres); laboratory personnel each separate location (EDs) - 2 sites reportedly experienced users of ID NOW (one ED and one urgent care centre) and 3 sites received training)
	Definition of test positivity: as per manufacturer
	Blinding reported: yes (RT-PCR performed at separate central lab)
	Timing of samples: not stated; on presentation

Study characteristics	
Patient Sampling	Single-group design to estimate sensitivity and specificity - samples from adult patients from 1 hospital and paediatric and adult samples from surrounding hospitals
	Recruitment: unclear; equal numbers of positive and negative RT-PCR samples (sus pect deliberate sampling by PCR result)
	Prospective or retrospective: not stated
	Number of samples (samples with confirmed SARS-CoV-2): 100 (50)
Patient characteristics and setting	Setting: hospital; not stated if inpatient or outpatient (samples selected from clini- cal virology laboratory)
	Location: Stanford Health Care (hospital), and surrounding hospitals (not named)
	Country: USA
	Dates: 7-13 April 2020
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: Accula SARS-CoV-2 POCT (no product code reported)
	Manufacturer: Mesa Biotech, Inc., San Diego, CA
	Antigen target: N gene
	Antibody: N/A
	Test method: rapid PCR
	Samples used: NP swabs in VTM (n = 37) or saline (n = 63, including 37 positive on RT-PCR)
	Transport media: not stated; 10 μL of VTM or saline was transferred to 60 μL of SARS-CoV-2 buffer within a biosafety cabinet (not covered by manufacturer IFU)
	Sample storage: not stated; testing appears to have been conducted soon after sample collection
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: as per manufacturer
	Blinding reported: not stated
	Timing of samples: not stated

Hogan 2020 (Continued)

Hou 2020

Study characteristics	
Patient Sampling	Single group study using remnant OP swabs submitted for SARS-CoV-2 testing at three medical centers (n = 285)
	Recruitment: Not stated
	Prospective or retrospective: Retrospective
Patient characteristics and setting	Setting: Mixed inpatient and outpatient
	Location: Three sites in Wuhan: Wuhan Tongji hospital (n=99), Wuhan Pulmonary hospital (n=96); Wuhan No. 1 hospital (n=90)
	Country: China
	Dates: Feb to Apr 2020
	Symptoms and severity: 178 (62.5%) inpatient; 107 (37.5%) outpatients. Site 2 were all inpatients
	Demographics: 220 (77.2%) aged ≤65 years; 159 (55.8%) male
	Exposure history: No details; all Wuhan
Index tests	Test name: Xpert Xpress (no product code reported)
	Manufacturer: Cepheid Inc
	Target gene(s): E, N2
	Antigen target: N/A
	Test method: Automated RT-PCR
	Samples used: OP
	Transport media: Not stated; 'aliquot made'
	Sample storage: stored at -80°C within 24 h of collection
	Test operator: Not stated
	Definition of test positivity: Not stated; presume as per manufacturer (company funded study) - no mention of presumptive positive results
	Blinding reported: Not stated
	Timing of samples: Not stated
Target condition and reference standard(s)	Reference standard: RT-PCR assays approved by Chinese National Medical Prod- ucts Administration (NMPA) for the detection of SARS-CoV-2
	Definition of non-COVID cases: As for cases; single negative RT-PCR
	Genetic target(s): Not stated
	Samples used: OP (same as for rapid test)
	Timing of reference standard: Not stated; conducted at time of sample collection
	Blinded to index test: Yes

Hou 2020 (Continued)	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Simultaneous (same swab); time period of frozen storage was not reported
	All patients received same reference standard: Yes, although could be different RT- PCR assays at different sites
	Missing data: None reported, no participant flow diagram reported
	Uninterpretable results: None reported
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported
	Unit of analysis: Patients; states 'samples from unique patients'
Comparative

Location: Molecular & Genomic Pathology Laboratory, Thomas Jefferson University Hospital, Philadelphia Country: USA
Hospital, Philadelphia Country: USA
Dates: April 23 to 26, 2020
Symptoms and severity: Not stated
Demographics: Not stated
Exposure history: Not stated
Index tests Test name: ID NOW (product code not reported)
Manufacturer: Abbott Laboratories
Target gene(s): RdRp
Antigen target: n/a
Test method: Isothermal PCR
Samples used: 'dry swabs' as per manufacturer EUA protocol
Transport media: None
Sample storage: No storage reported (appears to be immediate testing)
Test operator: Not stated; laboratory staff presumed
Definition of test positivity: As per manufacturer
Blinding reported: Not stated 'tested in parallel'
Timing of samples: Not stated
Target condition and reference standard(s) Reference standard: RT-PCR; cobas SARS-CoV-2 Test (Roche Molecular Systems, Inc., Pleasanton, CA) using a cobas 6800 analyzer (Roche Molecular Systems, Inc). Either target present considered positive
Definition of non-COVID cases: As above; single PCR negative required
Genetic target(s): ORF1/a, E gene
Samples used: Not specifically described for subset of paired samples, but for full co- hort NP and OP swabs in VTM used (400 uL)
Timing of reference standard: Not stated
Blinded to index test: Not stated; tested in parallel
Incorporated index test: No
Flow and timing Time interval between index and reference tests: Simultaneous (paired swabs)

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review)

Jokela 2020

Patient Sampling	Two group study to estimate sensitivity and specificity including NP or OP swab samples sent to university laboratory:
	[1] for SARS-CoV-2 testing (n=97),
	[2] pre-pandemic samples sent for testing due to suspicion of other respiratory virus infection (n=10)
	Recruitment: Not stated
	Prospective or retrospective: Not stated; presume retrospective

Jokela 2020 (Continued)	
	[Also reports results for third cohort of samples from participants attending ter- tiary care EDs (n=362), however index test is ineligible for this review (Novodiag))]
Patient characteristics and setting	Setting: Not reported
	Location: Helsinki University Hospital Laboratory (HUSLAB), Helsinki
	Country: Finland.
	Dates: Mar to May 2020
	Symptoms and severity: Not stated
	Demographics: Not stated
	Exposure history: Not stated
Index tests	Test name: Xpert Xpress (no product code reported)
	Manufacturer: Cepheid Inc
	Target gene(s): E, N2
	Antigen target: n/a
	Test method: Automated RT-PCR
	Samples used: NP or OP; no details on collection
	Transport media: Not stated
	Sample storage: Not stated
	Test operator: Not stated
	Definition of test positivity: Not stated; presume as per manufacturer - no men- tion of presumptive positive results
	Blinding reported: Not stated
	Timing of samples: Not stated
Target condition and reference standard(s)	Reference standard: RT-PCR, one of three assays including 1) in-house LDT, 2) cobas SARS-CoV-2 test kit (Roche), or 3) Amplidiag COVID-19 test on the Amplidi- ag Easy platform (Mobidiag)
	Definition of non-COVID cases: As above for COVID-19 suspects (single PCR neg- ative); for pre-pandemic either Allplex Respiratory Panel 1/2/3 (Seegene, Seoul, Republic of Korea) and two by xTAG RVP Fast (Luminex Diagnostics, Toronto, Canada).
	Genetic target(s): 1) N gene, 2) orf1ab and E, 3) orf1ab and N
	Samples used: NP or OP, as for index
	Timing of reference standard: Not stated
	Blinded to index test: Not stated
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Simultaneous (same samples)
	All patients received same reference standard: Yes (different assays)
	Missing data: 107 samples tested with Novodiag but only 90 for Xpert

lokela 2020 (Continued)			
	Uninterpretable results:	None reported	
	Indeterminate results (in	dex test): None reported	
	Indeterminate results (re	eference standard): None r	eported

Methodological quality			
Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Unclear		
Was a case-control design avoided?	Yes		
Did the study avoid inappropriate exclusions?	Unclear		
Did the study avoid inappropriate inclusions?	Unclear		
Could the selection of patients have intro- duced bias?		Unclear risk	
Are there concerns that the included patients and setting do not match the review ques- tion?			Unclear
DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecular tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Unclear		
If a threshold was used, was it pre-specified?	Unclear		
Could the conduct or interpretation of the in- dex test have introduced bias?		Unclear risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			Unclear
DOMAIN 3: Reference Standard			

Jokela 2020 (Continued)			
Is the reference standards likely to correctly classify the target condition?	No		
Were the reference standard results interpret- ed without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	
Are there concerns that the target condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference stan- dard?	Yes		
Did all patients receive the same reference stan-	Yes		
Did all patients receive the same reference stan- dard?			
Did all patients receive the same reference stan- dard? Were all patients included in the analysis? Did all participants receive a reference stan-	No		

Kruger 2020(a)

Study characteristics	
Patient Sampling	 Single group study to estimate sensitivity and specificity of three assays (each tested on a separate co-hort of individuals, and extracted as three entries Kruger 2020(a), Kruger 2020(b), Kruger 2020(c). Participants at risk for SARS-CoV-2 infection based on exposure to a confirmed case, suggestive symptoms, or travel to a high risk area, presenting at one of three sites: (1) drive-in testing station (n=1213) (2) a clinical ambulatory testing facility (n=1308) (3) secondary care facility (n=53)
	This entry (Kruger 2020(a)) relates to the 727 participants tested with assay (a) from Shenzhen Bioeasy Biotechnology; it is unclear whether some particpants may have receieved more than one assay *This study was also reported as three independent FIND evaluations; author contact advised including data from the Kruger et al pre-print
	Recruitment: Not stated; recorded as consecutive, as per FIND evaluation protocol
	Prospective or retrospective: Prospective
Patient characteristics and setting	Setting: Mixed; (1), (2) Community (drive-in or clinical ambulatory testing); (3) secondary care

Kruger 2020(a) (Continued)	Location: Three sites: (1) Heidelberg, Germany; (2) Berlin, Germany and (3) Liverpool University Hospital
	Foundation Trust, Liverpool
	Country: (1), (2) Germany, (3) UK
	Dates: April 17th and August 25th, 2020; dates varied by assay and site
	Whole sample:
	Symptomatic on testing day (n=1901/2355, 80.7%)
	N with prior negative test result (n=236/1928, 12.2%)
	Mean age (SD) (n=2405: 40.4y (14.3))
	Male (%) (n=1115/2361, 47.2%)
	Participants undergoing assay (a) (denominator back-calculated from n and %) Symptomatic on testing day: 564/694, 81.2%
	N with prior negative test result: 73/624, 11.7%
	Mean age (SD): 42.7y (14.9y)
	Male (%): 47.2%
Index tests	Study reports data for three Ag assays, each tested on a separate cohort of individuals. This entry (Kruger 2020(a)) relates to assay [A]. See Kruger 2020(b) and Kruger 2020(c) for assays (b) and (c)
	Test name: Bioeasy 2019-nCoV Ag Fluorescence Rapid Test Kit (Time-Resolved Fluorescence)
	Manufacturer: Shenzhen Bioeasy Biotechnology Co. Ltd., Guangdong Province, China
	Antibody: Not stated
	Antigen target: Not stated
	Test method: FIA
	Samples used: Drive-in centre: NP or OP; Other centres: combined NOP (OP conducted first) RT-PCR swab obtained first, then same technique repeated for Ag test.
	Transport media: None; used manufacturer supplied buffer solution as per IFU (for the Bioeasy assay, "the developer requested for pipettes to be used to transfer adequate quantities of liquid; in the IFU no pipette is needed and a nozzle is provided").
	Sample storage: Drive-in centre and ambulatory testing: tested on site (presume short time frame) Secondary care: transported on ice to a category 3 facility for testing RT-PCR swab obtained first, then same technique repeated for Ag test.
	Test operator: Drive-in and ambulatory clinic: POC evaluation Secondary care: laboratory staff
	Definition of test positivity: as per Analyzer Invalid results were repeated once using the remaining buffer according to the respective IFUs. Readouts were done within the recommended time for each Ag-RDT (10 minutes for Bioeasy, 15 minutes for Coris and 15 to 30 minutes for SD Biosensor).
	Blinding reported: Yes; "Staff performing the Ag-RDTs were blinded to results of RT-PCR tests and vice versa"
	Timing of samples: Overall: mean 5 days pso (SD 9.6); for this assay 7.0 days (SD 12.2);
Target condition and ref- erence standard(s)	Reference standard: RT-PCR; varied by site

Kruger 2020(c) (Continued)	
	Invalid results were repeated once using the remaining buffer according to the respective IFUs. Readouts were done within the recommended time for each Ag-RDT (10 minutes for Bioeasy, 15 minutes for Coris and 15 to 30 minutes for SD Biosensor).
	Blinding reported: Yes; "Staff performing the Ag-RDTs were blinded to results of RT-PCR tests and vice ver- sa"
	Timing of samples: Overall: mean 5 days pso (SD 9.6); this assay 3.7 days (SD 5.6)
Target condition and reference standard(s)	Reference standard: RT-PCR; varied by site Drive-in samples (Heidelberg): TibMolbiol (Berlin, Germany); the Allplex SARS-CoV-2 Assay from Seegene (Seoul, South Korea); or the Abbott (Illinois, US) RealTime 2019-nCoV assay Ambulatory testing (Berlin): Roche Cobas SARS CoV-2 assay (Pleasanton, CA United States) on the Cobas® 6800 or 8800 system; SARS CoV-2 assay from TibMolbiol (Berlin, Germany) Secondary care (UK): Genesig® Real-Time Coronavirus COVID-19 PCR assay (Genesig, UK) Samples that showed a signal above the threshold in the relevant RT-PCR target regions for each assay were considered to be positive
	Definition of non-COVID cases: As per cases; single negative result
	Genetic target(s): Not stated
	Samples used: Paired swabs; as per index test (RT-PCR swab obtained first,) Drive-in centre: NP or OP Other centres: combined NOP (OP conducted first)
	Timing of reference standard: As per index test
	Blinded to index test: Yes; "Staff performing the Ag-RDTs were blinded to results of RT-PCR tests and vice versa"
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Paired; simultaneous
	All patients received same reference standard: Yes (different assays)
	Missing data: 154 excluded following enrolment [116 2nd swab refused, 3 nose bleed after 1st swab, 3 in- sufficient time for both swabs, 31 other reasons, 1 no reason available]
	Uninterpretable results: 2 invalid (PCR negative); [B] 8 invalid (PCR negative); [C] 0 invalid reported PCR: 3 excluded as invalid (n=2) or not available (n=1)
	Indeterminate results (index test): None reported;
	Ease of use assessment reported: [A] a high number of test execution steps (including precision pipetting) challenges when performing multiple tests at the same time possibly hindering the test's wide-spread use [B] challenges due to inconsistent test result interpretation (often only very faint lines visible) and defi- ciencies in both the test kit quality and design [C] no dissatisfactory scores identified
	Indeterminate results (reference standard): None reported
	Unit of analysis: Patients
Comparative	
Notes	Study reports an ease of use assessment; for this assay:
	no dissatisfactory scores identified
	Funding: Study was supported by FIND, Heidelberg University Hospital and Charité – University Hospital internal funds. Pfizer funded the clinical team in Liverpool, UK.

Methodological quality	
------------------------	--

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Sele	ction		
Was a consecutive or random sample of pa- tients enrolled?	Yes		
Was a case-control de- sign avoided?	Yes		
Did the study avoid in- appropriate exclusions?	Yes		
Did the study avoid in- appropriate inclusions?	Yes		
Could the selection of patients have intro- duced bias?		Low risk	
Are there concerns that the included pa- tients and setting do not match the review question?			Low concern
DOMAIN 2: Index Test (A	Intigen tests)		
Were the index test re- sults interpreted with- out knowledge of the results of the reference standard?	Yes		
If a threshold was used,	Yes		
was it pre-specified?			
		Low risk	

DOMAIN 2: Index Test (Rapid molecular tests)

Kruger 2020(c) (Continued)

DOMAIN 3: Reference St	andard	
Is the reference stan- dards likely to correctly classify the target con- dition?	No	
Were the reference standard results inter- preted without knowl- edge of the results of the index tests?	Yes	
Reference standard does not incorporate result of index test?	Yes	
Could the reference standard, its conduct, or its interpretation have introduced bias?	High r	sk
Are there concerns that the target condi- tion as defined by the reference standard does not match the question?		High
DOMAIN 4: Flow and Tin	ning	
Was there an appropri- ate interval between in- dex test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients in- cluded in the analysis?	Yes	
Did all participants re- ceive a reference stan- dard?	Yes	
Were results presented per patient?	Yes	
Could the patient flow have introduced bias?	Low ri	sk

Lambert-Niclot 2020 (Continued)	
Patient Sampling	Single-group study to estimate sensitivity and specificity: - samples submitted for RT-PCR testing (n = 138)
	Recruitment: not stated
	Prospective or retrospective: unclear; testing conducted prospectively
	Number of samples (samples with confirmed SARS-CoV-2): 138 (94)
Patient characteristics and setting	Setting: not stated
	Location: samples collected from virology laboratories of 3 university hospital groups from Assistance-Publique-Hôpitaux de Paris (APHP), (Saint-Antoine-Tenon- Trousseau, Saint-Louis-Lariboisière and Kremlin Bicêtre-Paul Brousse)
	Country: France
	Dates: 1-15 April 2020
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: COVID-19 Ag Respi-Strip CORIS (no product code)
	Manufacturer: BioConcept, Gembloux, Belgium
	Antigen target: SARS-CoV-2 NP
	Antibody: monoclonal antibodies
	Test method: CGIA
	Samples used: NP swabs in VTM (collection process not described)
	Transport media: either of: COPAN UTM 3 mL, Virocult 1 mL, Eswab Amies 1 mL, 4MRT 3 mL, 0.9% NaCl buffer and cobas ROCHE
	Sample storage: no cooling or freezing step used
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: not stated; as per manufacturer
	Blinding reported: not stated
	Timing of samples: not stated; presume on presentation
Target condition and reference standard(s)	Reference standard: RT-PCR (different kits used including RealStar Altona®, Anato- lia®, cobas 6800 Roche®, Allplex™ 2019-nCoV Assay Seegene®)
	Definition of non-COVID cases: single negative PCR
	Genetic target(s): E gene
	Samples used: NP swabs (same as for index)
	Timing of reference standard: within a few hours after collection; time post onset of symptoms not reported
	Blinded to index test: unclear
	Incorporated index test: no

Lephart 2020 [A]

Study characteristics		
Patient Sampling	Single group study including samples from: [1] patients presenting to emergency department (n=75), or	
	Recruitment: Not stated	
	Prospective or retrospective: Not reported	

Lephart 2020 [A] (Continued)

Trusted evidence. Informed decisions. Better health.

	[Study also reports results for second group of recovering inpatients with previous- ly laboratory-confirmed COVID-19 (n=13); for purposes of this review only those in group [1] were included]
Patient characteristics and setting	Setting: [1] ED
	Location: Not stated; pathology lab at University of Michigan Medical School
	Country: USA
	Dates: 22 Apr to 5 May 2020
	Symptoms and severity: Not reported
	Demographics: Not reported
	Exposure history: Not reported
Index tests	Test name: [A] ID NOW (second index test [B] Xpert Xpress , extracted as Lephart 2020 [B]; two additional RT-PCR tests evaluated in study but not included in this review). No product codes reported
	Manufacturer: [A] Abbott Molecular
	Target gene: Not reported in paper
	Test method: [A] isothermal PCR
	Samples used: [A] Nasal; Presume collected by HCP but not reported
	Transport media: [A] None - transported dry swabs in sealed sterile collection bags
	Sample storage: [A] within 24h
	Test operator: Not stated; presume lab staff
	Definition of test positivity: Each assay was performed according to manufacturer's EUA instructions.
	Blinding reported: Not stated; unlikely
	Timing of samples: On presentation; timing pso not reported
Target condition and reference standard(s)	Reference standard: Composite: positive on >=2 of 4 NATs tested considered D+, in- cluding [A] ID NOW, [B] Xpert Xpress, [C] Simplexa COVID-19 Direct (Diasorin) (this was the standard of care assay), [D] RealTime m2000 SARS-CoV-2 Assay (Abbott Molecu- lar)
	Definition of non-COVID cases: Three negatives (on different assays) required for D-
	Genetic target(s): Not stated
	Samples used: NP swabs (Same as for Xpert Xpress)
	Timing of reference standard: Within 24h of sample collection (on presentation at ED); no further detail
	Blinded to index test: Not stated; seems unlikely
	Incorporated index test: Yes
Flow and timing	Time interval between index and reference tests: Same swab [B], or paired collection [A]
	All patients received same reference standard: Yes, all had all 4 assays

Lephart 2020 [A] (Continued)	Missing data: None report	ed, no participant flow di	agram reported
	Uninterpretable results: N	lone reported	
			ults, [B] 1 'invalid' result; not re- only) on Xpert Xpress or no result
	Indeterminate results (ref	erence standard): None re	eported
	Unit of analysis: Unclear;	text refers to 'patients' so	presumed patient-based

Notes	

Lieberman 2020	
Study characteristics	
Patient Sampling	Single-group study to estimate sensitivity and specificity: - samples submitted for clinical diagnostic testing (n = 169; not all samples analysed for all tests)
	Recruitment: not stated
	Prospective or retrospective: retrospective (residual samples)
	Number of samples (samples with confirmed SARS-CoV-2): 169 (87)
Patient characteristics and setting	Setting: not stated; sampled from laboratory
	Location: Washington State Public Health Laboratory
	Country: USA
	Dates: not stated
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: Xpert Xpress
	Manufacturer: Cepheid

Trusted evidence. Informed decisions. Better health.

Lieberman 2020 (Continued)				
	Antigen target: E, N2			
	Antibody: N/A			
	Test method: rapid PCR			
	Samples used: NP swabs (collection not described)			
	Transport media: 300 μL of VTM sample			
	Sample storage: all same-sample comparisons were performed on specimens stored at 4 °C for < 72 h with no freeze-thaws			
	Test operator: not stated; presume laboratory staff Common panel of 26 specimens tested at UW by the UW CDC EUA-based LDT or at Lab- Corp Seattle			
	Definition of test positivity: 1 of 2 targets detected was considered positive for all assays; Xpert Xpress data extracted as per IFU definition (positive = both targets or N gene posi- tive; E-gene-positive requires retest)			
	Blinding reported: not stated			
	Timing of samples: not stated			
	Also evaluates: [B] Hologic Panther Fusion RUO, [C] Hologic Panther Fusion EUA, [D] Diasorin Simplexa, [E] Roche cobas 6800			
	in same 26 samples and in additional residual specimens (n = 115) at UW (different N per test)			
Target condition and reference stan- dard(s)	Reference standard: RT-PCR; UW CDC EUA-based in-house test (positive if 1 of 2 targets detected - presume at < 40 Ct)			
	Definition of non-COVID cases: single negative PCR			
	Genetic target(s): NI, N2			
	Samples used: NP swabs, as for index test			
	Timing of reference standard: not stated			
	Blinded to index test: not stated			
	Incorporated index test: no			
	Time interval between index and reference tests: all testing conducted within 72 h			
	All participants received same reference standard: yes			
	Missing data: none reported, no participant flow diagram reported; review team exclud- ed data for 28 specimens comparing Panther Fusion with DiaSorin Simplexa			
	Uninterpretable results: not stated			
	Indeterminate results (index test): 'Inconclusive' results (i.e. 1 genetic target detected) were considered positive due to the high specificity of all assays and limited cross-reac- tivity seen for SARS-CoV-2 primer sets. For Xpert Xpress only 12/13 were positive accord- ing to IFU specifications on first test (both targets present, or N gene positive); on retest- ing the presumptive positive became positive (detection of E-gene but not N-gene)			
	Indeterminate results (reference standard): as for index test			
	Unit of analysis: not stated, only refers to samples

Liotti 2020 (Continued)			
Is the reference standards likely to cor- rectly classify the target condition?	No		
Were the reference standard results inter- preted without knowledge of the results of the index tests?	Yes		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its con- duct, or its interpretation have intro- duced bias?		High risk	
Are there concerns that the target con- dition as defined by the reference stan- dard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval be- tween index test and reference standard?	Yes		
Did all patients receive the same refer- ence standard?	Yes		
Were all patients included in the analysis?	Unclear		
Did all participants receive a reference standard?	Yes		
Were results presented per patient?	Yes		
Could the patient flow have introduced bias?		Unclear risk	

Loeffelholz 2020

Study characteristics	
Patient Sampling	Two-group study to estimate sensitivity and specificity for diagnosis of active disease - suspected patients referred for COVID-19 testing at 7 sites according to the local criteria (n = 486); sampled to enrich for RT-PCR-positive specimens (not further described)
	Recruitment: convenience (in addition, 1 site (LAC+USC) tested specimens from a 4-day point prevalence survey of patients presenting with COVID-19 symptoms)
	Prospective or retrospective: retrospective
	Number of samples (samples with confirmed SARS-CoV-2): 486 (220)
Patient characteris-	Setting: not stated
tics and setting	Location: 7 sites:
	Johns Hopkins University, Baltimore; LAC+USC Medical Centre, University of Southern California, Los Angeles; Manchester University NHS Foundation Trust Manchester;

Loeffelholz 2020 (Contin	ued)
	Mondor Hospital, Paris; New York City Dept. Health and Mental Hygiene, NYC; Niguarda Hospital, Milan; University Hospital, Newark.
	Country: USA, UK, France, Italy
	Dates: 1 March-2 April 2020
	Symptoms and severity: not stated
	Demographics: adults at all sites except New York City Dept. Health and Mental Hygiene and Niguarda Hospi- tal where all age groups were tested (ages not stated)
	Exposure history: not stated
Index tests	Test name: Cepheid Xpert Xpress SARS-CoV-2 (RUO version, no product code reported)
	Manufacturer: Cepheid Europe
	Antigen target: nucleocapsid gene (N2) and the envelope gene (E) (RUO version also detects RdRp gene but this does not contribute to definition of positive)
	Antibody: N/A
	Test method: automated point-of-care PCR
	Samples used: swabs (NP (n = 339), OP (n = 15), combined NP/OP in the same transport vial (n = 97)), and TA (n = 30):
	 Baltimore - 61 NP Los Angeles - 88 NP Manchester - 54 NP/OP, 11 NP Paris - 68 NP NYC - NP 11, OP 15, TA 30, NP/OP 43 Milan - 79 NP Newark - 21 NP
	Transport media: VTM (swabs), diluted in saline (TA). 1 site (Manchester) pretreated specimens with an equal volume (≥ 30-< 50% (w/w)) of a guanidine hydrochloride buffer and heated at 80 °C
	Sample storage: stored at −80 °C prior to index test, except at 1 site (University Hospital, Newark) where specimens were tested in real time, within 2 h by the Xpert test (n = 21).
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: as per manufacturer: if both targets are detected, or if only N2 is detected, the test reports a positive result. If only the E target is detected the test reports a presumptive positive result "because this target is shared among some members of the sarbecovirus subgenus of coronaviruses". The RUO version of the test shows the amplification curves and PCR cycle threshold for all 3 genetic targets. The study reports that "The EUA test version cartridge contains the same reagents as the RUO cartridge. The only difference between the tests is the software which in the EUA version allows the user to see amplification curves and results for the N2 and E targets only".
	Blinding reported: not stated
	Timing of samples: not stated, presume on presentation
Target condition and reference stan-	Reference standard: RT-PCR (sites using each kit not reported, added by review team based on number of samples per site and per RT-PCR kit)
dard(s)	 New York SARS-CoV-2 Real-time Reverse Transcriptase (RT)- PCR Diagnostic Panel; NYC Quest SARS-CoV-2 rRT-PCR (Quest Diagnostics, San Juan Capistrano, US); Los Angeles

Loeffelholz 2020 (Continued)

Trusted evidence. Informed decisions. Better health.

	 RealStar® SARS-CoV-2 RT-PCR Kit 1.0 (Altona Diagnostics, Hamburg, Germany); Baltimore and Paris GeneFinder COVID-19 Plus RealAmp Kit (ELITechGroup, Puteaux, France); Milan Allplex 2019-nCoV Assay (Seegene, Seoul, SK); Milan Charité Virology (Berlin, Germany) (in-house); Manchester Abbott RealTime SARS-CoV-2 Assay (Abbott, Des Plaines, US); Newark Simplexa COVID-19 Direct (DiaSorin, Cypress, US); Newark
	Definition of non-COVID cases: yes (performed prior to index test)
	Genetic target(s): different targets depending on RT-PCR test used:
	 New York Panel; N (N1, N2) Quest; N (N1, N3) RealStar; S, E GeneFinderTM; RdRp, E, N Allplex; RdRp, E, N Charité Virology; RdRp Abbott RealTime; RdRp, N Simplexa; ORF1ab, S
	Tie-breaker methods (for discrepant results), included: Hologic Panther Fusion (San Diego, USA), Tib-Molbi- ol LightMix Modular Wuhan Coronavirus E-gene RT-PCR (Roche, Basel, Switzerland); and the CDC assay (IDT primers and probes)
	Samples used: as for index test
	Timing of reference standard: as for index test
	Blinded to index test: no storage; tested in real time
	Incorporated index test: no
Flow and timing	Time interval between index and reference tests: same samples but index performed after frozen storage for undefined period of time except at University Hospital, Newark where specimens were tested in real time, within 2 h by the Xpert test
	All participants received same reference standard: no
	Missing data: 4 Xpert Xpress test results were lost permanently due to a single instrument computer malfunc- tion
	Uninterpretable results: 1 Xpert Xpress test was invalid due to a cartridge error (inadequate sample volume)
	Indeterminate results (index test) presumptive positive results on Xpert Xpress were not reanalysed by Xpert Xpress, but all discrepant results were reanalysed by a third RT-PCR method
	Indeterminate results (reference standard): specimens with inconclusive results by a test, and those with dis- crepant results between Xpert and the RT-PCR tests were analysed by a third RT-PCR method 1 FN result was inconclusive on Quest SARS-CoV-2, and negative on CDC RT-PCR; re-considered as TN Of 11 FPs (including 1 presumptive positive on Xpert Xpress), 2 were negative on both New York SARS-CoV-2 and Panther Fusion (remained as FPs), and 9 were negative on in-house RT-PCR but positive on Roche RT- PCR (reclassified as TP) In addition, 12 specimens (8 NP, 4 NP/OP) were inconclusive by the NY (RT)- PCR Diagnostic Panel and con- sidered positive for data analysis purposes in the study. Of these, 11 were positive by the Xpert test and 1 was presumptive positive (EUA version of Xpert test). In 4 of these only the N1 target was detected and in 8 only the N2 target was detected by the New York EUA method, all with Ct values > 36
	One NP specimen was inconclusive by the Quest SARS-CoV-2 rRT-PCR test and negative by the Xpert test. The
	Quest test reports inconclusive if only a single target (N1 or N3) is detected. They were unable to determine which target was detected by the Quest test. This specimen was negative by a tie-breaker NAAT.

lertens 2020	
Study characteristics	
Patient Sampling	Single-group study to estimate sensitivity and specificity for diagnosis of active disease: - samples from patients suspected of SARS-COV-2 infections (n = 328)
	Recruitment: random sampling of samples submitted to 3 laboratories 322/328 NP samples (NP swabs) were randomly selected
	Prospective or retrospective: retrospectively
	Number of samples (samples with confirmed SARS-CoV-2): 328 (132)
Patient characteristics and set- ting	Setting: unclear; samples from university laboratories (discussion states that no outpatient pop ulation has been sampled, therefore assume inpatients and HCW samples)
	Location: laboratories at Université Libre de Bruxelles (LHUB-ULB), UZ Leuven and Centre Hosp talier Universitaire Sart-Tilman (CHU) Liège
	Country: Belgium
	Dates: 19-30 March 2020
	Symptoms and severity: not reported
	Demographics: not reported
	Exposure history: unclear; 53/328 samples were from HCW
Index tests	Test name: COVID-19 Ag Respi-Strip
	Manufacturer: Coris BioConcept (Belgium)
	Antigen target: SARS-CoV and SARS-CoV-2 highly conserved nucleoprotein
	Antibody: monoclonal antibodies directed against SARS-CoV and SARS-CoV-2 highly conserved nucleoprotein antigen
	Test method: immunochromatographic assay using colloidal gold (CGIA)
	Samples used: remnant respiratory specimens (322 NP swabs, 4 NP aspirate and 2 BAL)
	Transport media: NP: flocked swab + UTM 3 mL (or 1 mL of Amies) (Copan, Brescia, Italy); NPA: 3 mL VTM (veal infusion broth (Difco, Becton Dickinson, Sparks, MD, USA) supplemented with bovine albumin (Sigma Aldrich, St Louis, MO, USA)) BAL: N/A
	Sample storage: not described
	Test operator: laboratory technician
	Definition of test positivity: visible reddish-purple band appearing at the Test line position (T)
	Blinding reported: not stated

Flow and timing	Time interval between index and reference tests: all 3 tests conducted within 72 h of sam- ple collection		
	All participants received same reference standard: no? (all received both RT-PCR tests, only discordant results on RT-PCR had record review)		
	Missing data: none reported, no participant flow diagram reported		
	Uninterpretable results: 2 results were invalid on ID NOW and were not retested (excluded)		
	Indeterminate results (index test): none reported		
	Indeterminate results (reference standard): discordant results between 2 RT-PCR assays had record review to determine presence/absence COVID-19 infection		
	Unit of analysis: participants (specimens from 200 unique participants)		
Comparative			
Notes	Funding: none reported (some reagents supplied from NIH)		
	Publication status: preprint		
	Source: medRxiv		
	Author COI: no COI statement was reported		

Moore 2020 (Continued)

Methodological quality

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	No		
Was a case-control design avoided?	No		
Did the study avoid inappropriate ex- clusions?	Unclear		
Did the study avoid inappropriate in- clusions?	Yes		
Could the selection of patients have introduced bias?		High risk	
Are there concerns that the includ- ed patients and setting do not match the review question?			High
DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecula	r tests)		
Were the index test results interpret- ed without knowledge of the results of the reference standard?	Unclear		
If a threshold was used, was it pre- specified?	Yes		
Could the conduct or interpretation of the index test have introduced bias?		Unclear risk	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?			High
DOMAIN 3: Reference Standard			
Is the reference standards likely to cor- rectly classify the target condition?	Yes		
Were the reference standard results in- terpreted without knowledge of the re- sults of the index tests?	Unclear		
Reference standard does not incorpo- rate result of index test?	Yes		

Moore 2020 (Continued)	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
Are there concerns that the target condition as defined by the refer- ence standard does not match the question?	Low concern
DOMAIN 4: Flow and Timing	
Was there an appropriate interval be- tween index test and reference stan- dard?	Yes
Did all patients receive the same refer- ence standard?	Yes
Were all patients included in the analy- sis?	Unclear
Did all participants receive a reference standard?	Yes
Were results presented per patient?	Yes
Could the patient flow have intro- duced bias?	Unclear risk

Moran 2020	
Study characteristics	
Patient Sampling	Single-group study to estimate sensitivity and specificity: - specimens collected from inpatients and ambulatory patients at the University of Chicago
	Recruitment: not stated
	Prospective or retrospective: not stated
	Number of samples (samples with confirmed SARS-CoV-2): 103 (42)
Patient characteristics and setting	Setting: inpatient and ambulatory; samples selected from central laboratory
	Location: Clinical Microbiology Laboratory, University of Chicago
	Country: USA
	Dates: not stated
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: Xpert Xpress SARS-CoV-2 assay (no product code)

Rapid, point-of-care antigen and molecular-based tests for diagnosis of SARS-CoV-2 infection (Review)

Moran 2020 (Continued)	Manufacturer: Cepheid, Sunnyvale, CA
	Antigen target: E, N (N2 region)
	Antibody: N/A
	Test method: rapid PCR
	Samples used: 8 nasal and 95 NP swabs
	Transport media: none described
	Sample storage: not stated
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: not stated; re-testing using Xpert Xpress was under- taken for an N-gene positive result due discrepancy with RT-PCR (not in line with IFU recommendation)
	Blinding reported: not stated
	Timing of samples: not stated
Target condition and reference standard(s)	Reference standard: Roche cobas SARS-CoV-2 assay on the cobas 6800 system (Roche Molecular Systems, Branchburg, NJ)
	Definition of non-COVID cases: single RT-PCR negative
	Genetic target(s): ORF1, E
	Samples used: nasal and NP swabs; same as for index test
	Timing of reference standard: not stated
	Blinded to index test: not stated
	Incorporated index test: no
Flow and timing	Time interval between index and reference tests: not stated; same sample and appear to have both been conducted soon after sample collection
	All participants received same reference standard: yes
	Missing data: none reported, no participant flow diagram reported
	Uninterpretable results: none reported
	Indeterminate results (index test): single FP (negative on E gene and low posi- tive on N gene) was retested with Xpert Xpress and considered negative on both targets
	Indeterminate results (reference standard): single FP was retested on RT-PCR and found to be repeatedly negative
	Unit of analysis: refers to participants
Comparative	
Notes	Funding: none described
	Publication status: accepted manuscript

Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Unclear		
Was a case-control design avoided?	Yes		
Did the study avoid inappropriate exclusions?	Unclear		
Did the study avoid inappropriate inclusions?	Unclear		
Could the selection of patients have introduced bias?		Unclear risk	
Are there concerns that the included patients and setting do not match the review question?			Unclear
DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecular tests)			
Were the index test results interpreted without knowledge of the results of the reference stan- dard?	Unclear		
If a threshold was used, was it pre-specified?	No		
Could the conduct or interpretation of the in- dex test have introduced bias?		High risk	
Are there concerns that the index test, its con- duct, or interpretation differ from the review question?			Unclear
DOMAIN 3: Reference Standard			
Is the reference standards likely to correctly clas- sify the target condition?	No		
Were the reference standard results interpret- ed without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpretation have introduced bias?		High risk	

Moran 2020 (Continued)

Are there concerns that the target condition as defined by the reference standard does not match the question? High

DOMAIN 4: Flow and Timing		
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference stan- dard?	Yes	
Were all patients included in the analysis?	Unclear	
Did all participants receive a reference standard?	Yes	
Were results presented per patient?	Yes	
Could the patient flow have introduced bias?		Unclear risk

Nagura-Ikeda 2020

Study characteristics	
Patient Sampling	Single group study of patients with laboratory confirmed COVID-19 referred for isolation and treatment (n=103); participants had undergone qRT-PCR tests using NP or OP swabs collected at public health institutes or hospitals (presumably symptomatic), asympto- matic patients were tested as a result of mass-screening due to an outbreak or family cluster
	Recruitment: Not stated
	Prospective or retrospective: NR; samples appear to be collected prospectively but states that patient information was retrospectively collected from the hospital electronic medical records.
Patient characteristics and setting	Setting: Inpatient and asymptomatic (admitted or quarantined)
	Location: Self-Defense Forces Central Hospital, Tokyo
	Country: Japan
	Dates: Feb 11 to May 13, 2020
	Symptoms and severity: 88 (85%) symptomatic, including 16 (15%) severe (showing clin- ical symptoms of pneumonia - dyspnea, tachypnea, saturation of percutaneous oxygen [SpO2] < 93%, and the need for oxygen therapy); 15 (15%) asymptomatic (including 4 pre- symptomatic)
	Demographics: IPD provided - median age 46, range 18-87; 66 (64%) male
	Exposure history: Not reported
Index tests	Test name: ESPLINE® SARS-CoV-2 (no product code reported) [Five other tests performed including RT-PCR and RT-LAMP, but not eligible for this re- view]
	Manufacturer: Fuji Rebio Inc

Trusted evidence. Informed decisions. Better health.

Nagura-Ikeda 2020 (Continued)	Antibody: NP
	Antigen target: Not stated
	Test method: LFA (no reader device required)
	Samples used: Saliva (self-collected)
	Transport media: None; around 500 μL saliva collected
	Sample storage: Stored at -80C until sample preparation
	Test operator: Not stated; implies laboratory staff
	Definition of test positivity: Not stated; appearance of test line implied
	Blinding reported: Not stated
	Timing of samples: saliva collected on admission to hospital; IPD reports this was median 7 days p.s.o (1-14)
Target condition and reference stan- dard(s)	Reference standard: RT-qPCR on initial presentation (RT-PCR was conducted on saliva samples as part of the study but this did not form part of the reference standard diagnosis)
	Definition of non-COVID cases: Single RT-PCR negative
	Genetic target(s): Not reported
	Samples used: NP or OP
	Timing of reference standard: On presentation or as part of mass screening; specific tim- ing in regard to symptom onset was not reported for the original RT-PCR and unclear if same day as saliva collection
	Blinded to index test: Yes
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Unclear; saliva collected on day of ad- mission to quarantine/hospital but NP/OP conducted at some point prior to that
	All patients received same reference standard: Yes
	Missing data: Not stated, no participant flow diagram reported
	Uninterpretable results: None reported
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported
	Unit of analysis: Patients

PHE 2020(c) [non-HCW tested]

Study characteristics	
Patient Sampling	Set of studies conducted by PHE and University of Oxford. This extraction relates to a single group study estimating sensitivity and specificity: - individuals presenting at a regional COVID-19 testing centre as part of a Phase 4 com- munity field service evaluation (n=1946; according to Table 3 of pre-print) See other PHE extractions for other sub-studies of Innova assay
	Recruitment: Not stated; presume consecutive
	Prospective or retrospective: Not stated
Patient characteristics and setting	Setting: regional COVID-19 testing centres as part of an NHS Test and Trace service evaluation involving the general public
	Location: Not stated
	Country: UK
	Dates: Not stated
	Symptoms and severity: Not stated, presumed 'mainly symptomatic' for purposes of review analyses
	Demographics: Not stated
	Exposure history: Not stated
Index tests	Test name: Innova SARS-CoV-2 Antigen Rapid Qualitative Test
	Manufacturer: Innova Medical Group
	Antibody: Not stated
	Antigen target: Not stated
	Test method: Not stated
	Samples used: Anterior nasal and combined oropharyngeal samples
	Transport media: Dry swab
	Sample storage: None; immediate testing
	Test operator: self-trained non-HCW ('Boots' member of staff); described in pre-print as an "operator" or as 'self-trained members of the public'.
	Definition of test positivity: Visual line; as per manufacturer

Trusted evidence. Informed decisions. Better health.

PHE 2020(c) [non-HCW tested] (Continued)	Blinding reported: Yes; conducted on site		
	Timing of samples: Not stated		
Target condition and reference standard(s)	Reference standard: RT-PCR; no details. The pre-print supplementary materials de- scribes using the 'Roche platform' under the Phase 3b heading, and also provides the following text under the Phase 2 evaluation heading "Unless otherwise stated, all RT- PCR testing was undertaken on the Roche Cobas [®] 6800 or 8800 system using their pro- prietary SARS-CoV-2 assay as per manufacturer's instructions (with off-board lysis us- ing AVL buffer (Qiagen) and 5% Triton-X100 (Sigma Aldrich)). This assay detects OR- F-1a/b as a SARS-CoV-2 specific target, and the E-gene as a pan-sarbecovirus target."		
	Definition of non-COVID cases: Cases only study		
	Genetic target(s): Not stated		
	Samples used: Not stated; paired swabs obtained		
	Timing of reference standard: As for index test		
	Blinded to index test: Not stated		
	Incorporated index test: No		
Flow and timing	Time interval between index and reference tests: Paired swabs; simultaneous		
	All patients received same reference standard: Yes		
	Missing data: Initial sample of 1946 reported, 27 failed, leaving 1919 for inclusion, how- ever data for only 1686 samples are provided in the pre-print (1314 PCR- in Table 3 and 372 PCR+ in text pg 7), a difference of 233 samples.		
	Uninterpretable results: Failure rate reported as 27/1946 failed, 1.4%		
	Indeterminate results (index test): Unclear		
	Indeterminate results (reference standard): Unclear		
	Unit of analysis: Patients

Methodological quality			
Item	Authors' judgement Risk of bias Applicability concerns		
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Yes		
Was a case-control design avoided?	Yes		

PHE 2020(c) [non-HCW tested] (Continued)			
Did the study avoid inappropriate exclu- sions?	Yes		
Did the study avoid inappropriate inclu- sions?	Yes		
Could the selection of patients have in- troduced bias?		Low risk	
Are there concerns that the included pa- tients and setting do not match the re- view question?			Low concern
DOMAIN 2: Index Test (Antigen tests)			
Were the index test results interpreted without knowledge of the results of the ref- erence standard?	Yes		
If a threshold was used, was it pre-speci- fied?	Yes		
Could the conduct or interpretation of the index test have introduced bias?		Low risk	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?			High
DOMAIN 2: Index Test (Rapid molecular tes	ts)		
DOMAIN 3: Reference Standard			
Is the reference standards likely to correct- ly classify the target condition?	No		
Were the reference standard results inter- preted without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its con- duct, or its interpretation have intro- duced bias?		High risk	
Are there concerns that the target con- dition as defined by the reference stan- dard does not match the question?			High
DOMAIN 4: Flow and Timing			

Could the patient flow have introduced bias?	High risk
Were results presented per patient?	Yes
Did all participants receive a reference standard?	Yes
Were all patients included in the analysis?	No
Did all patients receive the same reference standard?	Yes
PHE 2020(c) [non-HCW tested] (Continued)	

PHE 2020(d) [HCW tested]

Study characteristics	
Patient Sampling	Set of studies conducted by PHE and University of Oxford. This extraction relates to a single group study estimating sensitivity alone: - individuals presenting at one of 14 regional drive-through COVID-19 NHS test and trace centres as part of the FALCON C-19 (Facilitating Accelerated Clinical validation Of Novel diagnostics for COV- ID-19, 20/WA/0169, IRAS 284229) phase 3b study; those with a positive PCR result were asked to re- turn for a re-test within 5 days of the original test result. From the originally published report (Nov 2020) it appears that only participants with samples that were positive on PCR at the second sam- pling were included.
	PHE 2020(d) [HCW tested] is for health care worker tested samples, and PHE 2020(d) [Lab tested] is for laboratory scientist tested samples See other PHE extractions for other sub-studies of Innova assay
	Recruitment: Not stated; presume consecutive
	Prospective or retrospective: Prospective
	Number of samples (cases): 479 (479) ; 267 tested by HCWs, 212 tested by laboratory scientists
Patient characteristics and	Setting: NHS drive through test and trace centres; no further details
setting	Location: 14 regional centres
	Country: UK
	Dates: 17 Sept to 23 Oct 2020
	Symptoms and severity: Only described for all 421 included participants in PHE 2020(d) [HCW test- ed] and PHE 2020(d) [Lab tested] combined: Suppl Table 2 reports 40 (9.5%) asymptomatic, 59 (14%) with no data, leaving 322 with >=1 symptom recorded. It is not stated whether symptoms were present at the time of the original swab or at the time of the second sampling therefore data for the asymptomatic group have not been included in analyses.
	NB: text reports data for 41 asymptomatic and 344 symptomatic from the Phase 3b study (total n = 385)
	Demographics: For the 421 participants: median age 33 y, 168, 40% male
	Exposure history: Not stated
Index tests	Test name: Innova SARS-CoV-2 Antigen Rapid Qualitative Test

PHE 2020(d) [HCW tested] (Continu	^{ued)} Manufacturer: Innova Medical Group
	Antibody: Not stated
	Antigen target: Not stated
	Test method: Not stated
	Samples used: combined anterior nasal and oropharyngeal swabs (1 stored as a dry swab and 1 swab placed in VTM; swabs were self-collected
	Transport media: Dry swab
	Sample storage: None; immediate testing (delay to testing at PHE for [B] is unclear)
	Test operator: PHE 2020(d) [HCW tested] HCW on-site, PHE 2020(d) [Lab tested] Laboratory scien- tist at PHE
	Definition of test positivity: Visual line; as per manufacturer
	Blinding reported: Yes
	Timing of samples: Not stated
Target condition and refer- ence standard(s)	Reference standard: RT-PCR; no details. The pre-print supplementary materials describes using the 'Roche platform' under the Phase 3b heading, and also provides the following text under the Phase 2 evaluation heading "Unless otherwise stated, all RT-PCR testing was undertaken on the Roche Cobas® 6800 or 8800 system using their proprietary SARS-CoV-2 assay as per manufacturer's instructions (with off-board lysis using AVL buffer (Qiagen) and 5% Triton-X100 (Sigma Aldrich)). This assay detects ORF-1a/b as a SARS-CoV-2 specific target, and the E-gene as a pan-sarbecovirus target."
	Definition of non-COVID cases:
	Genetic target(s): Not stated
	Samples used: Appears to be combined NOP swabs in VTM; obtained at same time as second sam- pling for Ag testing (5 days after 1st positive PCR)
	Timing of reference standard: As for index test
	Blinded to index test: Not stated
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: appears to be simultaneous (if 2nd PCR result was used).
	All patients received same reference standard: Yes
	Missing data: Initial sample of 267 reported, 27 failed, leaving 240 for inclusion however data for only 223 HCW tested samples are provided in the pre-print (text pg 7). The original report (Nov 2020) documented 16 samples in this cohort that were either PCR- (n=15) or void (n=1) presumably at the time of the second sampling (as only PCR+ were invited for Ag testing. Although the numbers don't quite add up, it seems likely that this could explain the difference between the 240 and 223 samples.
	Uninterpretable results: Failure rates reported as: [A] 28/296, 10.4%; [B] 9/221, 4.2%
	Indeterminate results (index test): Unclear
	Indeterminate results (reference standard): Unclear
	Unit of analysis: Patients

Smithgall 2020 [A]

Study characteristics	
Patient Sampling	Two-group study to estimate sensitivity and specificity: - patients undergoing routine clinical testing by RT-PCR (n = 113)
	Recruitment: unclear; describes deliberate sampling of samples with high, medium and low Ct values on the reference standard RT-PCR
	Prospective or retrospective: unclear; residual swabs used but testing undertaken within 48 h of sample collection
	Number of samples (samples with confirmed SARS-CoV-2): 113 (88)
Patient characteristics and setting	Setting: inpatient and ED (n from each not reported)
	Location: not stated; author institution is Columbia University Irving Medical Centre
	Country: USA
	Dates: 8-13 April 2020
	Symptoms and severity: not stated
	Demographics: 111 adult (range 23-101 years; average 65 years for RT-PCR-positive and 43 years for RT-PCR-negative); 2 paediatric (age 1 day and 5 days) 61, 54% male
	Exposure history: not stated
Index tests	Test name:
	[A] ID NOW (see <u>Smithgall 2020</u> [B] for details of comparator test) (product codes not reported)
	Manufacturer: [A] Abbott
	Antigen target: [A] RdRp gene
	Antibody: N/A
	Test method: [A] isothermal PCR Samples used: residual NP swabs (collection not described)
	Transport media: 3 mL VTM (M4RT VTM; ThermoFisher Scientific, Waltham, MA) or UTM (UTM; Becton Dickinson and Co., Franklin Lakes, NJ)
	Sample storage: stored at 4 °C; testing completed within 48 h of sample collection
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: automated as per manufacturer
	Blinding reported: not stated
	Timing of samples: not stated; presume on admission or presentation at ED
Target condition and reference standard(s)	Reference standard: RT-PCR with cobas SARS-CoV-2 assay on the 6800 platform (Roche Diagnostics, Indianapolis, IN); threshold not stated, all Ct values < 37 on both target genes
	Definition of non-COVID cases: not stated; presume single RT-PCR negative
	Genetic target(s): ORF1 a/b, E-gene

Smithgall 2020 [B] (Continued)

Patient characteris- tics and setting	See Smithgall 2020 [A] for full study details and QUADAS-2 entries
Index tests	Test name: [B] Xpert Xpress (product codes not reported) (see Smithgall 2020 [A] for details of comparator test)
	Manufacturer: [B] Cepheid
	Antigen target: [B] N2, E genes
	Antibody: N/A
	Test method: [B] automated RT-PCR
	Samples used: residual NP swabs (collection not described)
	Transport media: 3 mL VTM (M4RT VTM; ThermoFisher Scientific, Waltham, MA) or UTM (UTM; Becton Dickin- son and Co., Franklin Lakes, NJ)
	Sample storage: stored at 4 °C; testing completed within 48 h of sample collection.
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: presumptive positive (only E gene present) considered positive (re-testing recom- mended on IFU)
	Blinding reported: not stated
	Timing of samples: not stated; presume on admission or presentation at ED
Target condition and reference stan- dard(s)	See Smithgall 2020 [A] for full study details and QUADAS-2 entries
Flow and timing	See Smithgall 2020 [A] for full study details and QUADAS-2 entries
Comparative	
Notes	See Smithgall 2020 [A] for full study details and QUADAS-2 entries

SoRelle 2020

Study characteristics	
Patient Sampling	Unclear design to estimate sensitivity and specificity: paired saliva and NP samples from participants symptomatic for COVID-19 (n=83) [Additional saliva samples included for comparison of ID NOW with Xpert Xpress; not extracted for this review] Recruitment: Not stated Prospective or retrospective: Not stated
Patient characteristics and setting	Setting: Unclear Location: From authors institutions: University of Texas Southwestern Med- ical Center, Dallas
	Country: USA

oRelle 2020 (Continued)	
	Dates: Not reported
	Symptoms and severity: Not reported
	Demographics: Not reported
	Exposure history: Not reported
Index tests	Test name: ID NOW (no product codes)
	Manufacturer: Abbott Diagnostics
	Antibody: Not stated
	Antigen target: n/a
	Test method: Isothermal PCR
	Samples used: Saliva; collection not described
	Transport media: Not stated
	Sample storage: Not stated
	Test operator: Not stated; presume lab staff
	Definition of test positivity: As per manufacturer
	Blinding reported: Not stated
	Timing of samples: Not stated; chart review of patients with FN results against either RT-PCR (NP) Xpert Xpress (Saliva) (n=9) showed 6/9 tested >2 weeks after symptom onset
Target condition and reference standard(s)	Reference standard: RT-PCR; either Xpert® Xpress SARS-CoV-2 (Cepheid) or Abbott RealTime SARS-CoV-2 (Abbott Molecular) RT-PCR assays; n per assay is not reported
	Definition of non-COVID cases: As for cases (single negative)
	Genetic target(s): Not stated
	Samples used: NP in VTM (paired)
	Timing of reference standard: Not stated
	Blinded to index test: Not stated
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Paired
	All patients received same reference standard: Yes
	Missing data: None reported, no participant flow diagram reported
	Uninterpretable results: None reported
	Indeterminate results (index test): None reported
	Indeterminate results (reference standard): None reported; presumptive positives not mentioned
	Unit of analysis: Patients?

Could the patient flow have introduced bias?

Unclear risk

Study characteristics	
Patient Sampling	Two group study to estimate sensitivity and specificity, in: [1] RT-PCR confirmed COVID-19 samples selected from a total of 88 positive samples during time period (n=62); [2] Random sample of RT-PCR negative samples selected from 1363 negative speci- mens tested during same time frame (n=100)
	Recruitment: Unclear for cases (may have been all 'initial' samples tested); random sample of non-cases
	Prospective or retrospective: Unclear
Patient characteristics and setting	Setting: Not stated; multiple clinical institutions
	Location: SRL Inc, Tokyo
	Country: Japan
	Dates: early April'' also later states 4 day period
	Symptoms and severity: Not stated; High viral load (< 25 Ct) - 32/60, 53% Low viral load (>=25 Ct) - 28/60, 47%
	Demographics: Not stated
	Exposure history: Not stated
Index tests	Test name: ESPLINE SARS-CoV-2 (no product code reported)
	Manufacturer: Fujirebio Inc
	Antibody: SARS-CoV-2 antigen (from IFU)
	Antigen target: Anti-SARS-CoV-2 monoclonal antibodies (mouse) (from IFU)
	Test method: LFA using alkaline phosphatase (ALP) labelled antibodies
	Samples used: NP; collection not reported
	Transport media: Not described
	Sample storage: Swabs mixed with sample treatment solution; no storage reported
	Test operator: Not stated; laboratory staff presumed
	Definition of test positivity: Visual line, as per manufacturer
	Blinding reported: Not stated
	Timing of samples: Not stated but all cases are first samples presumed by authors t be from patient suspected of SARS-CoV-2 for the first time; negative samples were 'probably from COVID-19 patients for monitoring purposes and to check for negative conversion'
Target condition and reference standard(s)	Reference standard: RT-PCR; QuantiTect Probe RT-PCR Kit (Qiagen).

Study characteristics	
Patient Sampling	Study reports data for two cohorts. Van der Moeren 2020(b) relates to cohort [2] Single group study to estimate sensitivity alone: patients with a positive PCR test re sult at one of twp community testing facilities who were retested at home within 72h o initial positive result (n=132) see Van der Moeren 2020(a) for data related to cohort [1] Single group study to estimat sensitivity and specificity: all adults presenting at a single community test centre for COVID-19 testing (n=354)

an der Moeren 2020(b) (Continued)	Recruitment: Unclear; implies 'all' those with positive PCR invited to participate			
	Prospective or retrospective: Prospective			
Patient characteristics and setting	Setting: Community			
	Location: Municipal Health Service (GGD) regional test centres at Breda or Roosendaal			
	Country: Netherlands			
	Dates: Sep 28 to Oct 6			
	Symptoms and severity: At time of home visit: Asymptomatic 3, 2% (2/3 still PCR +ve) Symptomatic 129 (123 still PCR +ve) Day <7 66, 50% Day >7 57, 43%			
	Demographics: Not stated			
	Exposure history: Not stated			
Index tests	Test name: BD Veritor System for Rapid Detection of SARS-CoV-2			
	Manufacturer: Becton Dickinson			
	Antibody: NP			
	Antigen target: Not stated			
	Test method: LFA; no further detail			
	Samples used: NOP? "specimen from the throat and the superficial nasal cavities (bilat- eral, 2.5 cm proximal from the nostril)"; collected by GGD employee			
	Transport media: Direct testing			
	Sample storage: stored dry in sterile test tubes and stored and transported on dry ice until processing at the laboratory; tested within 6 hours after collection			
	Test operator: trained laboratory technicians			
	Definition of test positivity: reported using Analyzer (included in main analysis for re- view), and by naked eye inspection alone			
	Blinding reported: Not stated			
	Timing of samples: Not reported; on presentation			
Target condition and reference stan-	Reference standard: RT-PCR; either Cobas 6800 (Roche) or the m2000 (Abbott).			
dard(s)	Definition of non-COVID cases: n/a			
	Genetic target(s): E- and RDRP-gene (Roche) or E-gene and N-gene (Abbott)			
	Samples used: NOP; specimen from the throat and nasal cavity up to the nasal bridge			
	Timing of reference standard: As for index test			
	Blinded to index test: Not stated			
	Incorporated index test: No

Item	Authors' judgement	Risk of bias	Applicability concerns	
DOMAIN 1: Patient Selection				
Was a consecutive or random sample of patients enrolled?	Unclear			
Was a case-control design avoided?	No			
Did the study avoid inappropriate exclu- sions?	Yes			
Did the study avoid inappropriate inclu- sions?	Yes			
Could the selection of patients have in- troduced bias?		High risk		
Are there concerns that the included patients and setting do not match the review question?			High	
patients and setting do not match the			High	
patients and setting do not match the review question?	Unclear		High	

Van der Moeren 2020(b) (Continued)			
Could the conduct or interpretation of the index test have introduced bias?		Unclear risk	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?			High
DOMAIN 2: Index Test (Rapid molecular te	ests)		
DOMAIN 3: Reference Standard			
Is the reference standards likely to cor- rectly classify the target condition?	No		
Were the reference standard results inter- preted without knowledge of the results of the index tests?	Unclear		
Reference standard does not incorporate result of index test?	Yes		
Could the reference standard, its con- duct, or its interpretation have intro- duced bias?		High risk	
Are there concerns that the target con- dition as defined by the reference stan- dard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval be- tween index test and reference standard?	Yes		
Did all patients receive the same refer- ence standard?	Yes		
Were all patients included in the analysis?	No		
Did all participants receive a reference standard?	Yes		
Were results presented per patient?	Yes		
Could the patient flow have introduced bias?		High risk	

Veyrenche 2020

 Study characteristics

 Patient Sampling
 Two group study estimating sensitivity and specificity:

 [1] PCR+ hospital inpatients (n=45)

 [2] pre-pandemic samples from 'patients' (not otherwise specified) (n=20)

Veyrenche 2020 (Continued)	Recruitment: Not stated; appears to be convenience as equal numbers per Ct value
	subgroup Prospective or retrospective: Retrospective
Patient characteristics and setting	Setting: Inpatient
Patient Characteristics and setting	
	Location: Montpellier University hospitals (Centre Hospitalier Universitaire de Montpellier, Montpellier)
	Country: France
	Dates: 14 March to 11 April
	Symptoms and severity: 27/45, 60% cases 'severe' according to WHO guideline (similar numbers per Ct subgroup)
	Demographics: Median age: Ct<=25 - 66 (IQR 48, 84) Ct 25-35 - 63 (50, 76) Ct>=35 - 58 (49-67) Controls 64 (35, 93); 32/45, 71% male, all controls were male
	Exposure history: Not stated
Index tests	Test name: Coris COVID-19 Ag Respi-Strip
	Manufacturer: BioConcept®, Gembloux, Belgium
	Antibody: NP
	Antigen target: monoclonal ab
	Test method: CGIA
	Samples used: NP; collection not described
	Transport media: Yes; "swabs were collected in various transport media (eSwab™ COPAN Amies 1 ml, Σ-Transwab® liquid Amies, viral transport medium tube VTM-M 2.0ml)."
	Sample storage: Unclear; RT-PCR conducted prospectively within a few hours but not reported for Ag testing
	Test operator: Not stated; presume lab staff
	Definition of test positivity: Visual, as per manufacturer
	Blinding reported: Not stated
	Timing of samples: day 1 to 20 pso, median Ct<=25 - 7 (4, 10; presume this is IQR but could be range - is described as SD in pa- per) Ct 25-35 - 8 (4, 12) Ct>=35 - 11 (7, 15)
Target condition and reference standard(s)	Reference standard: RT-PCR; Allplex™ 2019-nCoV Assay (Seegene, Seoul, South Ko- rea)
	Definition of non-COVID cases: pre-pandemic
	Genetic target(s): RdRp, N, E
	Samples used: NP; as for index

Wolters 2020

Study characteristics	
Patient Sampling	2-group study to estimate sensitivity and specificity for diagnosis of active disease: - samples selected from laboratories on the basis of presence/absence of 2 genetic targets on RT-PCR: SARS-CoV-2 E-gene +/RdRp gene + (n = 30); SARS-CoV-2 E-gene +/RdRp gene – (n = 28); SARS-CoV-2 E-gene -/RdRp gene (n = 30) (A separate set of samples were tested in triplicate at all 3 laboratories to determine limits of de- tection and analytical specificity)
	Recruitment: not stated; deliberate sampling used
	Prospective or retrospective: retrospective
	Sample size (cases): 88 (58)
Patient characteristics and set-	Setting: not stated; 3 laboratories
ting	Location: Radboud UMC in Nijmegen, PAMM in Veldhoven and the RIVM in Bilthoven
	Country: The Netherlands
	Dates: January-March 2020
	Symptoms and severity: not stated
	Demographics: not stated
	Exposure history: not stated
Index tests	Test name: Cepheid Xpert Xpress SARS-CoV-2 (product code not reported)
	Manufacturer: Cepheid Europe
	Antigen target: E-gene (sarbeco-specific) and N2-gene (SARS-CoV-2-specific)

Wolters 2020 (Continued)	Antibody: N/A
	Test method: not stated (it should be automated PCR)
	Samples used: NP or mid-turbinate, and OP swabs
	Transport media: UTM or GLY medium; no further details
	Sample storage: stored at -80c
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: as per manufacturer; reported E-gene-only positive specimens as presumptive positive but no re-testing with Xpert Xpress was reported. N2-only positives were considered positive (but re-tested with RT-PCR)
	Blinding reported: not stated (see comment section)
	Timing of samples: not stated
Target condition and reference standard(s)	Reference standard: in-house RT-PCR: Radboud UMC Lab: MagNApure 96 (Roche) (isolation platform); MagNApure 96 DNA and Viral NA Small Volume (extraction kit); Roche LC480 II (PCR platform); Life Technologies Taqman FastVirus 1-step mastermix (RT-PCR mastermix) PAMM Lab: Roche cobas 4800 (isolation platform); CT/NG extraction protocol (extraction kit); Roche LC480 II (PCR platform); Roche LightCycler Multiplex RNA Virus Master (RT-PCR master- mix); RIVM Lab: BioMérieux NucliSens (isolation platform); easyMAG EasyMAG extraction reagents (ex- traction kit); Thermo Fisher QuantStudio 6 (PCR platform); Life Technologies Taqman FastVirus
	1-step mastermix (RT-PCR mastermix)
	Definition of non-COVID cases: yes (performed prior to index test)
	Genetic target(s): Radboud UMC lab: E-gene and RdRp-gene PAMM Lab: started with E-gene and RdRp-gene and mid-March moved on to E-gene testing only RIVM Lab: started with E-gene and RdRp-gene and at the beginning of April moved on to E-gene and CDC N1-gene primer and probes
	Samples used: as for index test
	Timing of reference standard: as for index test
	Blinded to index test: storage prior to freezing was not reported; samples were analysed at or near time of collection ("processed in the routine diagnostic procedure using the locally implemented RT-PCR")
	Incorporated index test: no
Flow and timing	Time interval between index and reference tests: same samples used; index text seems to have been conducted after frozen storage
	Missing data: none reported, no participant flow diagram reported
	Uninterpretable results: none reported
	Indeterminate results (index test): 1 sample was positive only on N2 gene (positive according to IFU) and 1 was positive only on E gene (presumptive positive, requires re-testing according to IFU). Both samples were re-tested on RT-PCR only
	Indeterminate results (reference standard): re-testing of the two 'FN' samples (one TP and 1 presumptive positive according to IFU definition) with RT-PCR found both samples to be disease-negative (reclassed as 1 TN and 1 FP); study authors note that the viral loads of these samples are at the limit of detection for Xpert Xpress and that multiple freeze-thaw steps of samples could have had a significant impact on detection.

Wolters 2020 (Continued)

Are there concerns that the in- dex test, its conduct, or inter- pretation differ from the re- view question?			High
DOMAIN 3: Reference Standard			

Wolters 2020 (Continued)			
Is the reference standards like- ly to correctly classify the target condition?	No		
Were the reference standard re- sults interpreted without knowl- edge of the results of the index tests?	Yes		
Reference standard does not in- corporate result of index test?	Yes		
Could the reference standard, its conduct, or its interpreta- tion have introduced bias?		High risk	
Are there concerns that the tar- get condition as defined by the reference standard does not match the question?			High
DOMAIN 4: Flow and Timing			
Was there an appropriate interval between index test and reference standard?	Yes		
Did all patients receive the same reference standard?	Yes		
Were all patients included in the analysis?	Unclear		
Did all participants receive a ref- erence standard?	Yes		
Were results presented per pa- tient?	Unclear		
Could the patient flow have in-		Unclear risk	

Nong 2020	
Study characteristics	
Patient Sampling	Single group study to estimate sensitivity and specificity: - samples submitted for routine testing from patients with suspected COVID-19 infection presenting at A&E (n=93), in-patient (n=47) or outpatient n=18) (total n=158 providing 162 samples)
	Recruitment: Not stated
	Prospective or retrospective: Both retrospective (n=74) and prospective (n=88)
Patient characteristics and setting	Setting: Mixed; A&E, inpatient and outpatient

Wong 2020 (Continued)	Location: Prince of Wales Hospital, Hong Kong
	Country: China
	Dates: Not stated
	Symptoms and severity: Not stated
	Demographics: Median age 46 (IQR: 35(28-63); males = 69 (44%)
	Exposure history: Not stated
Index tests	Test name: Xpert Xpress
	Manufacturer: Cepheid Inc
	Antibody: E and N2
	Antigen target: n/.a
	Test method: Automated RT-PCR
	Samples used: deep throat saliva (DTS) (n=120), or lower respiratory tract (LRT) (n=42; 35 sputum, 6 tracheal aspirate 1 BAL)
	Transport media: None; collected in plain sterile container. Prior to testing, PBS was added to was added into neat DTS specimens (ratio 1:1) and vortexed for homogenization and allowed to settle for 5- 10 min. 2mL of homogenized sample transferred to another vial for centrifugation at 2000 g for 5 min. 1mL of LRT specimens added to 3 mL of in-house prepared Maintenance Medium (MM) (10X Mini- mum Essential Medium (MEM), 200 mM glutamine, 1 M HEPES, 7.5 % NaHCO3, 12 mg gentamicin, 0.5 mg amphotericin B, 10,000 units penicillin, 10 mg streptomycin, pH 7.1– 7.4); mixture was emulsified by pipetting up and down, followed by centrifugation at 2000 g for 5 min. Supernatant was used for testing as per manufacturer's instructions for both RT-PCR and Xpert Xpress
	Sample storage: transported to laboratory on the same day and tested promptly
	Test operator: Lab staff
	Definition of test positivity: As per manufacturer; presumptive positives mentioned only in Introduction section
	Blinding reported: Not stated
	Timing of samples: Not stated
Target condition and reference stan- dard(s)	Reference standard: RT-PCR; TIB-Molbiol LightMix® SarbecoV E-gene assay; all positive cases confirmed by reference laboratory of Hong Kong (Public Health Laboratory Service Branch, PHLSB).
	Definition of non-COVID cases: As for cases (single negative)
	Genetic target(s): Not stated
	Samples used: DTS or LRT; as per index test
	Timing of reference standard: Not stated
	Blinded to index test: Yes; conducted first (upon receipt, all samples were screened with our standard-of-care assay)
	Incorporated index test: No
Flow and timing	Time interval between index and reference tests: Simultaneous (Same samples)

Wong 2020 (Continued)			
	All patients received same	e reference standard: Yes	
	Missing data: None report	ed	
	Uninterpretable results: N	one reported	
	Indeterminate results (ind	lex test): None reported	
	Indeterminate results (ref	erence standard): None rep	orted
	Unit of analysis: Samples	(162/158)

Methodological quality			
Item	Authors' judgement	Risk of bias	Applicability concerns
DOMAIN 1: Patient Selection			
Was a consecutive or random sample of patients enrolled?	Unclear		
Was a case-control design avoided?	Yes		
Did the study avoid inappropriate exclusions?	Unclear		
Did the study avoid inappropriate inclu- sions?	Unclear		
Could the selection of patients have in- troduced bias?		Unclear risk	
Are there concerns that the included patients and setting do not match the review question?			Unclear
DOMAIN 2: Index Test (Antigen tests)			
DOMAIN 2: Index Test (Rapid molecular t	ests)		
Were the index test results interpreted without knowledge of the results of the reference standard?	Unclear		
If a threshold was used, was it pre-speci- fied?	Unclear		
Could the conduct or interpretation of the index test have introduced bias?		Unclear risk	

Vong 2020 (Continued) Are there concerns that the index test, its conduct, or interpretation differ from the review question?			High	
DOMAIN 3: Reference Standard				
Is the reference standards likely to cor- rectly classify the target condition?	No			
Were the reference standard results inter- preted without knowledge of the results of the index tests?	Yes			
Reference standard does not incorporate result of index test?	Yes			
Could the reference standard, its con- duct, or its interpretation have intro- duced bias?		High risk		
Are there concerns that the target con- dition as defined by the reference stan- dard does not match the question?			High	
DOMAIN 4: Flow and Timing				
Was there an appropriate interval be- tween index test and reference standard?	Yes			
Did all patients receive the same refer- ence standard?	Yes			
Were all patients included in the analysis?	Unclear			
Did all participants receive a reference standard?	Yes			
Were results presented per patient?	No			
Could the patient flow have introduced bias?		High risk		

oung 2020		
Study characteristics		
Patient Sampling	Single group study to estimate sensitivity and specificity: - Patients with one or more symptoms of COVID-19 (within <=7 days post symptom onset) at 21 study sites (n=260) [Second cohort of 361 samples from COVID suspects <=5 days p.s.o. also evaluated to compare BD Veritor with Quidel Sofia® 2 SARS Antigen FIA but excluded from review as only discrepant results on the two Ag assays underwent RT-PCR] Recruitment: Not stated Prospective or retrospective: Prospective	

Young 2020 (Continued)	
Patient characteristics and setting	Setting: Mixed; drive-through/tent (n=42), outpatient clinic (n=74), research clinic (n=72), or skilled nursing facility (n=66)
	Location: Unclear; 21 geographically diverse study sites [Author institutions BD Life Sciences, Louisiana State University Health Sciences Center, Tricore Reference Laboratory)
	Country: USA
	Dates: June 5-11, 2020
	Symptoms and severity: 110 (43%) cough, 98 (39%) muscle pain, 95 (37%) headache, 90 (35%) sore throat, 90 (35%) sore throat, 78 (31%) fever. Of those at <=6 days p.s.o (n=245): 94 (38%) with one symptom, 151 (62%) with >= 2 symptoms
	Demographics: median age 43 (range 18 to 90); 91 (36%) male
	Exposure history:
Index tests	Test name: BD Veritor SARS-CoV-2 antigen test (no product codes)
	Manufacturer: Becton, Dickinson and Company, BD Life Sciences—Integrated Diagnostic Solu- tions, San Diego, CA
	Antibody: NP
	Antigen target: not stated
	Test method: Not stated; chromatographic immunoassay with analyser
	Samples used: Nasal; clinician collected from both nostrils (same swab)
	Transport media: dry nasal swabs
	Sample storage: Swabs were shipped for testing on dry ice (-70°C);
	Test operator: Not stated; Veritor testing was performed internally at BD (San Diego, CA, USA)
	Definition of test positivity: As per manufacturer
	Blinding reported: Yes; all personnel blinded to all other test results
	Timing of samples: All <=7 days p.s.o; median 3.0 d, mean 3.2 d. 38 (15%) 1 day p.s.o, 57 (23%) 2 days, 54 (22%) 3 days, 40 (16%) 4 days, 37 (15%) 5 days, 19 (8%) 6 days, 6 (2%) 7 days
Target condition and reference standard(s)	Reference standard: Lyra® SARS-CoV-2 PCR Assay (Quidel Corporation. Athens, OH); BD MAX™ real time SARS-CoV-2 PCR assay used for discordant testing
	Definition of non-COVID cases: As for cases (single negative)
	Genetic target(s): Not stated
	Samples used: NP (n= 217) or OP (n=34); clinician collected (if an NP swab was collected as part of SOC, the participant had the option of having an OP study swab taken in lieu of a second NP swab)
	Timing of reference standard: Swabs taken prior to any study swabs (potential for contamina- tion of nasal cavity)
	Blinded to index test: Yes; performed at TriCore Reference Laboratories. "All testing was conducted with all personnel blinded to all other test results"
	Incorporated index test: No
	Time interval between index and reference tests: Simultaneous (paired)

Young 2020 (Continued)			
	All patients received same	reference standard: Yes	
	Missing data: 9 excluded; 6 (2 on RT-PCR and 1 labellir		ria and 3 had invalid specimens/results
	Uninterpretable results: 3	invalid on at least one assay	
	Indeterminate results (ind	ex test): None reported	
	-	onfirmed FN (BD MAX +ve an	rted. Re-test of 9 'FN' results with BD d sero +ve), 6 were BD Max -ve (incl 1

Zhen 2020 [A]

Study characteristics	
Patient Sampling	2-group study to estimate sensitivity and specificity: - samples from symptomatic patients of all ages and gender
	Recruitment: not stated; specimens selected to represent the true positivity rate at au- thors' institution (50% to 60%), and to span low and high viral loads
	Prospective or retrospective: mixed; included frozen samples (n = 88) and prospectively tested (n = 20)
	Number of samples (samples with confirmed SARS-CoV-2):108 (58)
Patient characteristics and setting	Setting: not stated; selected from laboratory
	Location: not stated; authors' institutions were Northwell Health Laboratories, and Dept Pathology and Laboratory Medicine, The Donald and Barbara Zucker School of Medicine
	Country: USA
	Dates: March-April 2020
	Symptoms and severity: "symptomatic"; no further details
	Demographics: not stated (all ages and genders)
	Exposure history: not stated
Index tests	Zhen 2020 [A] is the entry for test [A] from the list below
	Test name:
	[A] Xpert® Xpress SARS-CoV-2 [B] ID NOW COVID-19 (no product codes reported)
	Manufacturer: [A] Cepheid, [B] Abbott
	Antigen target: [A] N2, E; [B] RdRp
	Antibody: N/A
	Test method: rapid PCR
	Samples used: NP swabs
	Transport media: UTM (various manufacturers)
	Sample storage: on collection, stored at 2-8 °C for up to 72 h; after routine testing, stored at -80 °C 88 samples tested using ePlex on collection, then frozen prior to testing with ID NOW, Xpert Xpress and Hologic RT-PCR; 20 samples tested prospectively after collection on all systems
	Test operator: not stated; presume laboratory staff
	Definition of test positivity: not stated; states "testing was performed according to the manufacturer's instructions" but no presumptive positives reported
	Blinding reported: not stated
	Timing of samples: not stated

Zhen 2020 [A] (Continued)	Study also evaluates [C] G	enMarkePley® SARS-CoV-2 T	Fest (not eligible for this review)
Target condition and reference stan-			GARS-CoV-2 assay, performed ac-
dard(s)	cording to manufacturer's		
	Definition of non-COVID ca	ases: single RT-PCR

APPENDICES

Appendix 1. Summary of World Health Organization and Chinese National Health Commission Guidelines for the diagnosis of SARS-CoV-2

Table A: World Health Organization guidelines for the diagnosis of SARS-CoV-2^a

Includes laboratory testing guidelines and global surveillance guidelines

Date range (2020)	Definition of confirmed case	Definition of confirmed non-case	Definition of suspect case	Definition of probable case	Role of serology in testing
10-30 January 2020	 10-30 January: no documentation to define at this time (before first date of global guidelines) 31 January onwards: a confirmed case is a person with laboratory confirmation of COVID-19 infection, irrespective of clinical signs and symptoms. No prescribed test in laboratory guidelines, suggested tests from 10 January include broad coronavirus RT-PCR (with sequencing of precise virus in test positives), whole genome sequencing, broad coronavirus serology on paired samples, microscopy, culture (Lab 10 January). Four suggested tests from 17 January: broad coronavirus RT-PC 	None stated	No definition of 'suspect case' at this time, but case definitions for surveillance are defined as a combina- tion of symp- toms and ex- posure, with more severe symptoms re- quiring less evidence for exposure	No definition at this time	Serological test- ing may be use- ful to confirm immunologic response to a pathogen from a specific viral group, e.g. coro- navirus. Best re- sults from sero- logic testing re- quires the col- lection of paired serum samples (in the acute and convalescent phase) from cas-
31 January-26 February 2020		None stated	Suspect case defined as combination of symptoms and exposure, with more se- vere symp- toms requir- ing less evi- dence for ex- posure	A suspect case with inconclu- sive laborato- ry results or is test-positive using a pan- coronavirus assay without laboratory ev- idence of oth- er respirato- ry pathogens (global 31 January)	es under investi- gation.
27 February-1 March 2020	-	None stated	Suspect case defined as	A suspected case with in-	
2 March-19 March 2020	A person with laboratory confirmation of COVID-19 infection, irrespective of clinical	One or more negative re-	 combination of symptoms and exposure, 	conclusive laboratory re- sults	In cases where NAAT assays are

(Continued)	signs and symptoms (global 31 January, 27 February, 20 March) – Laboratory confirmation of cases by NAAT	sult does not rule out the possibility	with more se- vere symp- toms requir-	(global 27 February)	negative and there is a strong - epidemiologi-
19 March 2020-current (12-03-21)	 Laboratory commutation of cases by NAAA specific to SARS-CoV-2 such as real-time RT-PCR with confirmation by nucleic acid sequencing when necessary. The viral genes targeted so far include the N, E, S and RdRP genes. In areas with no known COVID-19 virus circulation confirmation requires: NAAT-positive for at least two different targets on the COVID-19 virus genome, of which at least one target is preferably specific for COVID-19 virus (or SARS-like coronavirus) using a validated assay; OR NAAT-positive result for betacoron- avirus, and COVID-19 virus identified by sequencing partial/whole genome of virus (sequence target larger or dif- ferent from the amplicon probed in the NAAT assay). Discordant results should be resampled. In areas where COVID-19 virus is wide- ly spread a simpler algorithm might be adopted (e.g. RT-PCR of a single discrimi- natory target) 	of COVID-19 virus infection	ing less evi- dence for ex- posure, OR defined by symptoms re- quiring hospi- talisation and an absence of alternative ex- planation	Probable case A suspect case for whom testing for the COVID-19 virus is incon- clusive OR A suspect case for whom test- ing could not be performed for any rea- son.	 cal link to COV- ID-19 infection, paired serum samples (in the acute and con- valescent phase) could support di- agnosis once val- idated serology tests are avail- able. Serological as- says will play an important role in research and sur- veillance but are not currently rec- ommended for case detection.

NAAT: nucleic acids amplification test; RT-PCR: reverse transcription polymerase chain reaction

^aSource data from Laboratory testing of 2019 novel coronavirus (2019-nCoV) in suspected human cases: interim guidance, World Health Organization. 10 January, 17 January, 2 March, 19 March, 21 March 2020 (WHO 2020d), and Global surveillance for COVID-19 caused by human infection with COVID-19 virus, interim guidance, 31 January, 27 February, and 20 March 2020 (WHO 2020e).

Table B: Summary of Chinese National Health Commission guidelines for diagnosis and treatment for novel coronavirus pneumonia (trial versions 1-7)

Dates in effect	Definition of confirmed case	Definition of con- firmed non-case	Definition of suspect case	Role of serology in testing
16-17 January 2020 (version 1)	Cases (not confirmed cases) de- fined as virus genome highly ho- mologous to coronaviruses	Not defined	Observation cases: defined as combination of exposure in Wuhan and symptoms focused on pneu- monia, leukopenia and lack of im- provement.	No role
18 January-2 March 2020 (ver- sions 2, 3, 4, 5, 5 revised, and 6)	 Suspect cases with either real-time fluorescent RT-PCR indicates positive for new coronavirus nucleic acid; OR viral gene sequence is highly homologous to known new coronaviruses 	Suspect cases can be ruled out after 2 consecutive neg- ative respiratory tract nucleic acid tests taken at least 24 hours apart.	Suspect cases: combination of ex- posure (such as residence in/trav- el to Wuhan or exposure to a con- firmed case within 14 days of on- set) AND clinical features (such as symptoms: fever, respiratory symptoms, and tests: chest imag- ing, white blood cell and lympho-	No role

cyte count). Exact definition varies slightly with version

3 March 2020- current (12-03-21 (version 7)	 Suspect cases with either real-time fluorescent RT-PCR indicates positive for new coronavirus nucleic acid; OR viral gene sequence is highly homologous to known new coronaviruses OR NCP virus-specific IgM and IgG are detectable in serum; NCP virus-specific IgG is detectable or reaches a titration of at least 4-fold increase during convalescence compared with the acute phase. 	Suspect cases can be ruled out after 2 negative NAATs, taken at least 24 hours apart, and the NCP virus-spe- cific IgM and IgG are negative after 7 days from onset.	Suspect cases: combination of exposure (such as residence in/travel to Wuhan or exposure to a confirmed case within 14 days of onset) AND clinical features (such as symptoms: fever, respiratory symptoms, and tests: chest imaging, white blood cell and lymphocyte count).	Part of definition of cases and con- firmed non-cases

Appendix 4. Search classification model

We needed a more efficient approach to keep up with the rapidly increasing volume of COVID-19 literature. A classification model for COVID-19 diagnostic studies was built with the model building function within Eppi Reviewer, which uses the standard SGCClassifier in Scikit-learn on word trigrams. As outputs, new documents receive a percentage (from the predict_proba function) where scores close to 100 indicate a high probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document' and scores close to 0 indicate a low probability of belonging to the class 'relevant document'. We used three iterations of manual screening (title and abstract screening, followed by full-text review) to build and test classifiers. The final included studies were used as relevant documents, while the remainder of the COVID-19 studies were used as irrelevant documents. The classifier was trained on the first round of selected articles, and tested and retrained on the second round of selected articles revealed poor positive predictive value but 100% sensitivity at a cut-off of 10. The poor positive predictive value is mainly due to the broad scope of our topic (all diagnostic studies in COVID-19), poor reporting in abstracts, and a small set of included documents. The model was retrained using the articles selected of the second and third rounds of screening, which added a considerable numb

Appendix 7. Criteria for assessment of study quality (QUADAS-2)

DOMAIN: Participant selection	
Was a consecutive or random	This will be similar for all index tests, target conditions, and populations.
sample of patients enrolled?	Yes: if a study explicitly stated that all participants within a certain time frame were included; that this was done consecutively; or that a random selection was done.
	No: if it was clear that a different selection procedure was employed; for example, selection based on clinician's preference, or based on institutions, or based on result of RT-PCR
	Unclear: if the selection procedure was not clear or not reported
Was a case-control design avoided?	This will be similar for all index tests, target conditions, and populations.
avoided?	Yes: if a study explicitly stated that all participants came from the same group of (suspected) pa- tients.
	No: if it was clear that a different selection procedure was employed for the participants depending on their COVID-19 status or SARS-CoV-2 infection status; or if only participants with SARS-CoV-2 infection were included
	Unclear: if the selection procedure was not clear or not reported.
Did the study avoid inappro- priate exclusions?	Studies may have excluded patients, or selected patients in such a way that they avoided including those who were difficult to diagnose or likely to be borderline. Although the inclusion and exclusion criteria will be different for the different index tests, inappropriate exclusions and inclusions will be similar for all index tests: for example, only elderly patients excluded, or children (as sampling may be more difficult). This needs to be addressed on a case-by-case basis.
	Yes: if a high proportion of eligible patients was included without clear selection.
	No: if a high proportion of eligible patients was excluded without providing a reason; if, in a retro- spective study, participants without index test or reference standard results were excluded.
	Unclear: if the exclusion criteria were not reported.
Did the study avoid inappro- priate inclusions?	Some laboratory studies may have intentionally included groups of patients in whom the accura- cy was likely to differ, such as those with particularly low or high viral loads, or who had other dis- eases, such that the sample over-represented these groups. This needs to be addressed on a case- by-case basis.
	Yes: if samples included were likely to be representative of the spectrum of disease.
	No: if the study oversampled patients with particular characteristics likely to affect estimates of ac- curacy.
	Unclear: if the exclusion criteria were not reported.
Could the selection of pa- tients have introduced bias?	High: if one or more signalling questions were answered with no, as any deviation from the selec- tion process may lead to bias.
	Low: if all signalling questions were answered with yes.

(Continued)			
	Unclear: all other instances		
Is there concern that the in- cluded participants do not match the review question?	High: for two-group studies that included healthy or other disease controls, whether pre-pandemic or contemporaneous; studies that only included people with COVID-19 (whether RT-PCR-confirmed only, participants meeting official guideline criteria);		
	Low: for single-group studies recruiting participants with signs and symptoms of COVID-19; or for two-group studies where control groups suspected of COVID-19 were separately recruited.		
	Unclear: if a description about the participants was lacking.		
DOMAIN: Index tests			
Were the index test results interpreted without knowl-	Yes: if blinding was explicitly stated or index test was recorded before the results from the refer- ence standard were available.		
edge of the results of the ref- erence standard?	No: if it was explicitly stated that the index test results were interpreted with knowledge of the re- sults of the reference standard.		
	Unclear: if blinding was unclearly reported.		
If a threshold was used, was it prespecified?	Yes: if the test was dichotomous by nature, or if the threshold was stated in the methods section, or if study authors stated that the threshold as recommended by the manufacturer was used.		
	No: if a receiver operating characteristic curve was drawn or multiple threshold reported in the re- sults section; and the final result was based on one of these thresholds.		
	Unclear: if threshold selection was not clearly reported.		
Could the conduct or inter- pretation of the index test	High: if one or more signalling questions were answered with no, as even in a laboratory situation knowledge of the reference standard may lead to bias.		
have introduced bias?	Low: if all signalling questions were answered with yes.		
	Unclear: all other instances		
Is there concern that the in- dex test, its conduct, or in- terpretation differ from the review question?	For all test types, if index test is 'in-house' or not commercially available, then state 'High'. If any test procedures used in the study diverged from IFU ((use of VTM, or testing outwith stated time limit), also state High If testing carried out in centralised laboratory and not near patient then state High. Evaluations that withheld the name of the test, or that used mixed sample types or did not report the evaluation setting, state Unclear If samples used and any sample processing steps are in accordance with test IFU, or if study de- scribes conducting the test according to the manufacturer's protocol, state Low		
DOMAIN: Reference standard			
Is the reference standard likely to correctly classify	We will define acceptable reference standards using a consensus process once the list of reference standards that have been used has been obtained from the eligible studies.		
the target condition?	For COVID-19 cases		
	Yes: RT-PCR; confirmed or suspected case using official criteria (WHO, CDC) or a clearly set out com- bination of signs/symptoms/exposure		
	No: RT-PCR not used, or if inadequate combination of clinical characteristics used in PCR-nega- tives, e.g. computed tomography alone		
	Unclear: if definition of COVID-19 was not reported		
	For absence of COVID-19		

'Continued)				
	Yes: if at least 2 negative RT-PCR results reported if suspected COVID-19 based on signs/symptoms; single negative RT-PCR test for asymptomatic contacts or contemporaneous controls with no clinical suspicion of COVID-19; only pre-pandemic sources of control samples used.			
	No: single RT-PCR or number of negative RT-PCRs not reported for COVID-19 suspects; no RT-PCR reported (untested) for asymptomatic contacts or contemporaneous controls Unclear: if timing of control samples (pre-pandemic or contemporaneous) was not reported			
Were the reference standard results interpreted without knowledge of the results of	Yes: if it was explicitly stated that the reference standard results were interpreted without knowl- edge of the results of the index test, or if the result of the index test was obtained after the refer- ence standard.			
the index test?	No: if it was explicitly stated that the reference standard results were interpreted with knowledge of the results of the index test or if the index test was used to make the final diagnosis.			
	Unclear: if blinding was unclearly reported.			
Did the definition of the ref-	Yes: if results from the index test were a component of the reference standard definition.			
erence standard incorpo- rate results from the index	No: if the reference standard did not incorporate the index standard test.			
test(s)?	Unclear: if it was unclear whether the results of the index test formed part of the reference stan- dard.			
Could the conduct or inter-	High: if one or more signalling questions were answered with no.			
pretation of the reference standard have introduced	Low: if all signalling questions were answered with yes.			
bias?	Unclear: all other instances			
Is there concern that the tar-	Applicability was judged primarily on the definition of disease-positive.			
get condition as defined by the reference standard does	High: if RT-PCR alone used to define cases			
not match the review ques- tion?	Low: if clinical criteria, including RT-PCR, were used to define cases, regardless of whether official criteria were explicitly described.			
	Unclear: if definition of COVID-19 cases was not provided, including if some clinically diagnosed cases were included but the clinical criteria used were not described.			
DOMAIN: Flow and timing				
Was there an appropriate in- terval between index test	Yes: if same swab used, or swabs obtained at same time regardless of freezing (which is covered under index applicability)			
and reference standard?	No: if different samples used with more than 24 hours between collection times			
	Unclear: if can't tell			
Did all participants receive	Yes: if all participants received the same reference standard (clearly no differential verification).			
the same reference stan- dard?	No: if (part of) the index test-positives or index test-negatives received a different reference stan- dard.			
	Unclear: if it was not reported			
Were all participants includ-	Yes: if it is clear that all eligible participants were included in the analyses.			
ed in the analysis?	No: if after the inclusion/exclusion process, participants were removed from the analyses for dif- ferent reasons: no reference standard done, no index test done, intermediate results of both index test or reference standard, indeterminate results of both index test or reference standard, samples unusable.			

(Continued)	Unclear: if it is not possible to determine whether all participants were included (e.g. from a STARD- style participant flow diagram)
Did all participants receive a	Yes: if all participants received a reference standard (clearly no partial verification).
reference standard?	No: if only (part of) the index test positives or index test negatives received the complete reference standard.
	Unclear: if it was not reported
Were results presented per participant?	Yes: if either only one sample per participant (regardless of disaggregation of results over time), or if multiple samples per participant but results are disaggregated by time period (at least week by week)
	No: if multiple samples per participant and results are not disaggregated by time period
	Unclear: if it is not possible to tell whether results presented are per participant or per sample
Could the participantflow	High: if one or more signalling questions were answered with no.
have introduced bias?	Low: if all signalling questions were answered with yes.
	Unclear: all other instances

Appendix 8. Excluded studies

Study	Exclusion reason	Notes	Other review inclusion				
Studies 'almost' included							
Basu 2020	Ineligible reference standard	Assesses agreement between two POC tests	No; excluded				
FIND 2020f	Superseded by Kruger 2020(a)	Coris Bioconcept data	No; excluded				
McDonald 2020	Ineligible reference standard	Only antigen negatives get RT-PCR	No; excluded				
McCormick-Baw 2020	Ineligible reference standard	RT-PCR (including Xpert XPress) using alter- native sample types	Sampling methods compar- ison				
Mlcochova 2020	superseded by Collier 2020	SAMBA-II data (33 COVID cases; same re- cruitment dates	No; excluded				
Studies excluded o	on index test technology						
Anahtar 2020	Ineligible index test	in-house RT-LAMP; direct testing	Technology comparison				
Ar Gouilh 2020	Ineligible index test	in-house RT-LAMP	Technology comparison				
Arumugam 2020	Ineligible index test	in-house RT-PCR; direct testing	Technology comparison				
Azzi 2020	Ineligible index test	in-house RT-LAMP	Technology comparison				

Continued)			
Baek 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Bokelmann 2020	Ineligible index test	Cap-iLAMP (capture and improved loop-me- diated isothermal amplification).	Technology comparison
Bordi 2020	Ineligible index test	One step RT-PCR; not suited to POC	Technology comparison
Broughton 2020	Ineligible index test	in-house CRISPR-Cas12 based assay	Technology comparison
Chen 2020a	Ineligible index test	CRISPR/Cas12a	Technology comparison
Chow 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Ding 2020a	Ineligible index test	in-house RT-LAMP	Technology comparison
Dong 2020	Ineligible index test	One-step RT-dPCR	Technology comparison
Fowler 2020	Ineligible index test	(direct) RT-LAMP	Technology comparison
Freire-Paspuel 2020b	Ineligible index test	compares two RT-PCR kits	No; excluded
Hirotsu 2020	Ineligible index test	Automated RT-PCR; not suited to POC	No; excluded
Hu 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Huang 2020	Ineligible index test	in-house Rt-LAMP	Technology comparison
James 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Jiang 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Joung 2020	Ineligible index test	SHERLOCK testing in one Pot	Technology comparison
Joung 2020a	Ineligible index test	in-house RT-LAMP	Technology comparison
Lee 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Lu 2020a	Ineligible index test	in-house RT-LAMP	Technology comparison
Mohon 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Newman 2020	Ineligible index test	in-house RT-LAMP used in mobile setting; sample prep includes centrifuge	Technology comparison
Osterdahl 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Peto 2020	Ineligible index test	loop-mediated isothermal amplification and nanopore sequencing	Technology comparison
Pollock 2020a	Ineligible index test	Laboratory-based Ag assay	Technology comparison
Qian 2020	Ineligible index test	Fast isothermal Nucleid acid detection (FIND) assay (RT-RPA)	Technology comparison
Rauch 2020	Ineligible index test	CREST - CRISPr-Cas13a	Technology comparison

(Continued)

Shirato 2020	Ineligible index test	Intended for direct testing but used with ex- tracted RNA	Technology comparison
Singh 2020b	Ineligible index test	targeted-mass spectrometry	Technology comparison
Wang 2020a	Ineligible index test	RT-RAA assay	Technology comparison
Wang 2020a	Ineligible index test	CRISPR/Cas12a-based assay with a naked eye readout, CRISPR/Cas12a-NER	Technology comparison
Yan 2020	Ineligible index test	in-house RT-LAMP	Technology comparison
Yang 2020b	Ineligible index test	in-house RT-LAMP	Technology comparison
Yu 2020a	Ineligible index test	in-house RT-LAMP	Technology comparison
Yu 2020b	Ineligible index test	in-house RT-LAMP (iLACO)	Technology comparison
Yu 2020c	Ineligible index test	LFA technology but sample requires PCR amplification step first	Technology comparison
Zhang 2020	Ineligible index test	(RT-LAMP) coupled with nanoparti- cles-based biosensor (NBS) assay (RT-LAMP- NBS)	Technology comparison
Zhu 2020	Ineligible index test	RT-LAMP with extracted RNA	Technology comparison

LFA: lateral flow assay; PCR: polymerase chain reaction; POC: point-of-care; RT-LAMP: reverse transcription loop-mediated isothermal amplification; RT-PCR: reverse transcription polymerase chain reaction

				were from swabs im- mersed in VTM prior to use		
Innova Medical Group; In- nova SARS- CoV-2 Anti- gen Rapid Qualitative Test IFU: A/02	CGIA Single test 20-30 min	Provides: test car- tridge, extraction tube, extraction so- lution, QC card 2-30 °C	Nasal or OP; intend- ed for use within the first 5 days of the onset of symp- toms	Not men- tioned	Test ASAP after collection. Based on data generat- ed with influen- za virus, throat swabs are stable for up to 24 h at room temperature or 2°-8 °C	Visual: negative if control line only; positive if both test and control lines ap- pear no matter how faint; invalid if no control line vis- ible
Liming Bio-Prod- ucts Co., Ltd; COV- ID-19 Anti- gen Rapid Test Device (StrongStep®)	CGIA Single test 15 min	Test device, extrac- tion buffer vial, extraction tubes, workstation for holding tubes 2-30 °C	NP or OP	Not men- tioned in IFU	ASAP; can be held in clean, dry plas- tic tube or sleeve up to 72 h at 15-30 °C, or 2-8 °C before processing	Visual; 2 coloured bands for positive; control band only for negative; test line only is invalid
IFU: ob- tained via Weitzel 2020 [A]; REF 500200 v1						
Quidel; Sofia SARS Antigen FIA IFU: 1439000EN00 (04/20)	FIA Single test 15 min	Provided: test cassette, reagent tubes, reagent solu- tion, nasal swabs, 120 μL fixed volume pipette, SARS pos- itive control swab, negative control swab Required: Sofia or Sofia 2 reader de- vice, Calibration Cassette 15 °C-30 °C	Nasal or NP	Updated IFU: direct- ly test pa- tient speci- mens with- out trans- port media. Original IFU: if transport of samples with VTM is required, minimal di- lution of the sample is recom- mended, e.g. ≤ 1 mL	Test ASAP after collection. Based on data generat- ed with influen- za virus, nasal or NP swabs are sta- ble for up to 24 h at room tempera- ture or 2-8 °C, and nasal or NP swabs in VTM are stable for up to 72 h at 2-8 °C	The Sofia screen will display results for the procedur- al control as being 'tick' or 'cross', and will individually provide a '+' or '-' result for SARS. If the procedural con- trol is 'X' retest with a new patient sample and a new test cassette. Results must not be interpreted past 30 minutes after inoculation
RapiGEN Inc; BIO- CREDIT COVID-19 Ag	CGIA Single test 5-8 min	Test device, assay diluent tube and fil- ter cap, swab for NP collection; 1-40 °C	NP swab	Not men- tioned in IFU	Test ASAP after collection; if stor- age required then 2-8 °C for up to 12 h, or −20 °C for up to 24 h	Visual; control line only (negative), control and test lines (positive), no control line (invalid)

Appendix 18. Planned heterogeneity investigations

Test subgroups	Number of studies						
Sample type	Overall	Other or mixed					
Antigen tests	n = 48						
NP only	32	19	8	5			
Nasal	2	1	1				
Saliva	1	1	-	-			
NP+OP	5	2	3	-			
NP or OP or combined NP + OP or nasal (≥ 2 evalu- ated)	7	5	1	1			
BAL or throat wash	1	0	0	1			
Rapid molecular tests	n = 30						
NP only	14	3	9	2			
OP only	1	-	-	1			
Nasal	2	2					
Saliva	1	-	-	1			
NP+OP	2	1	1	0			

(Continued)					
NP or OP or NOP or nasal (≥ 2)	7	-	-	7	
Throat saliva or LRT	1	-	-	1	
Stool	1	-	-	1	
Not stated	1	1	-	-	

BAL: bronchoalveolar lavage; LRT: lower respiratory tract; NP: nasopharyngeal; OP: oropharyngeal, VTM: viral transport medium

WHAT'S NEW

Date	Event	Description
24 March 2021	Amended	Correction of typo in abstract

HISTORY

Review first published: Issue 8, 2020

Date	Event	Description
24 March 2021	Amended	Amendment to PLS title
9 March 2021	New citation required and conclusions have changed	This review has been updated and the conclusions have changed
30 September 2020	New search has been performed	We have updated our review and now include 64 study reports in 78 study cohorts, evaluating 16 antigen and 5 molecular assays

CONTRIBUTIONS OF AUTHORS

JD was the contact person with the editorial base.

JDI co-ordinated contributions from the co-authors and wrote the final draft of the review.

JJD, JDi, YT, CD, STP, IH, AA, LFR, MP, MT, JDr, SB screened papers against eligibility criteria.

RS conducted the literature searches.

JDi, MT and AA appraised the quality of papers.

JDi, MT and AA extracted data for the review and sought additional information about papers.

JDi entered data into Review Manager 2020.

JDi, JJD, YT and SB, analysed and interpreted data.

JJD, JDi, YT, CD, STP, RS, ML, LH, AVB, DE, SD, JC worked on the methods sections and commented on the draft review.

JJD and JDi responded to the comments of the referees.

JJD is the guarantor of the update.

DECLARATIONS OF INTEREST

Jonathan J Deeks: JD has published or been quoted in opinion pieces in scientific publications, and in the mainstream and social media related to diagnostic testing. JD was the statistician on the Birmingham evaluation of the Innova test which is mentioned in the discussion of the paper. There was no funding for this evaluation of the Innova test. JD is a member of the Royal Statistical Society (RSS) COVID-19 taskforce steering group, and co-chair of the RSS Diagnostic Test Advisory Group. He is a consultant adviser to the WHO Essential Diagnostic List. JD receives payment from the BMJ as their Chief Statistical advisor.

Devy Emperador: is employed by FIND with funding from DFID and KFW. FIND is a global non-for profit product development partnership and WHO Diagnostic Collaboration Centre. It is FIND's role to accelerate access to high-quality diagnostic tools for low-resource settings and this is achieved by supporting both R&D and access activities for a wide range of diseases, including COVID-19. FIND has several clinical research projects to evaluate multiple new diagnostic tests against published Target Product Profiles that have been defined through consensus processes. These studies are for diagnostic products developed by private sector companies who provide access to know-how, equipment/reagents, and contribute through unrestricted donations as per FIND policy and external SAC review.

Sabine Dittrich: is employed by FIND with funding from DFID and Australian Aid. FIND is a global non-for profit product development partnership and WHO Diagnostic Collaboration Centre. It is FIND's role to accelerate access to high-quality diagnostic tools for low-resource settings and this is achieved by supporting both R&D and access activities for a wide range of diseases, including COVID-19. FIND has several clinical research projects to evaluate multiple new diagnostic tests against published Target Product Profiles that have been defined through consensus processes. These studies are for diagnostic products developed by private sector companies who provide access to know-how, equipment/reagents, and contribute through unrestricted donations as per FIND policy and external SAC review.

SOURCES OF SUPPORT

Internal sources

- Liverpool School of Tropical Medicine, UK
- University of Birmingham, UK

External sources

• Department for International Development, UK

Project number: 300342-104

- National Institute for Health Research (NIHR), UK
- NIHR Birmingham Biomedical Research Centre at the University Hospitals Birmingham NHS Foundation Trust and the University of Birmingham, UK

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We planned to check the following websites for eligible index tests, however these did not prove to be very accessible or easy to use and, after initial review, were not further considered:

- National Institute for Health Research (NIHR) Innovation Observatory (www.io.nihr.ac.uk/)
- www.rapidmicrobiology.com/test-method/testing-for-the-wuhan-coronavirus-a-k-a-covid-19-sars-cov-2-and-2019-ncov

We planned to check the following evidence repository for additional eligible studies however, the EPPI-Centre and Norwegian Institute of Public Health resources proved to be more accessible therefore we decided to prioritise our other sources of evidence.

Meta-evidence (meta-evidence.co.uk/the-role-of-evidence-synthesis-in-covid19/)

We intended for two authors to independently perform data extraction, however one review author extracted study characteristics, and a second author checked them. Contingency table data were extracted independently by two review authors as planned.

We planned to evaluate the effect of additional sources of heterogeneity, including reference standard and sample type. However, additional formal investigations using meta-regression were not possible because of lack of variability across the studies in these features.

We planned to conduct a sensitivity analysis excluding studies that are solely published as preprints. We have inadequate study numbers to allow this at present but will reconsider for the next update.

INDEX TERMS

Medical Subject Headings (MeSH)

Antigens, Viral [analysis]; *Betacoronavirus; Clinical Laboratory Techniques [*methods]; Coronavirus Infections [*diagnosis] [epidemiology]; COVID-19; COVID-19 Testing; False Negative Reactions; False Positive Reactions; Pandemics; Pneumonia, Viral [*diagnosis] [epidemiology]; *Point-of-Care Systems; SARS-CoV-2; Sensitivity and Specificity
