The transcriptional regulator c-MYC is abnormally overexpressed in many human cancers. Evasion from apoptosis is critical for cancer development, particularly c-MYC-driven cancers. We explored which anti-apoptotic BCL-2 family member (expressed under endogenous regulation) is essential to sustain c-MYC-driven lymphoma growth to reveal which should be targeted for cancer therapy. Remarkably, inducible Cre-mediated deletion of even a single Mcl-1 allele substantially impaired the growth of c-MYC-driven mouse lymphomas. Mutations in p53 could diminish but not obviate the dependency of c-MYC-driven mouse lymphomas on MCL-1. Importantly, targeting of MCL-1 killed c-MYC-driven human Burkitt lymphoma cells, even those bearing mutations in p53. Given that loss of one allele of Mcl-1 is well tolerated in healthy tissues, our results suggest that therapeutic targeting of MCL-1 would be an attractive therapeutic strategy for MYC-driven cancers.

Supplemental material is available for this article.

Received October 1, 2013; revised version accepted November 19, 2013.

The c-MYC transcription factor regulates ~10,000 genes, including many that control cell growth and division (Dang 1999). Deregulated c-MYC expression is detected in up to 70% of human cancers, including lymphomas and leukemias (Boxer and Dang 2001; Sanchez-Beato et al. 2003). Much of what we know about c-MYC-driven tumorigenesis has emerged from studies using Eμ-Myc transgenic mice, in which the c-Myc transgene is subjugated to the immunoglobulin (Ig) heavy chain gene enhancer (Eμ), mimicking the consequences of the c-MYC/IGH or c-MYC/IGL chromosomal translocations that drive human Burkitt lymphoma (Adams et al. 1985). The Eμ-Myc mice exhibit a preleukemic expansion of pre-B cells that precedes the outgrowth of clonal slg+ pre-B-cell or slg− B-cell lymphomas arising with a median latency of ~110 d (Adams et al. 1985; Langdon et al. 1986).

Evasion from cell death is a hallmark of cancer, particularly those driven by c-MYC (Hanahan and Weinberg 2011; Kelly and Strasser 2011). Deregulated c-MYC expression enhances cell death under unfavorable growth conditions, such as limited availability of growth factors, through the intrinsic apoptotic pathway that is regulated by interactions of proteins belonging to three functionally distinct subgroups of the BCL-2 family (Youle and Strasser 2008). Following apoptotic stimuli, the proapoptotic BH3-only proteins (e.g., BIM and PUMA) become transcriptionally and/or post-transcriptionally up-regulated. For example, in response to DNA damage or oncogenic stress, the tumor suppressor p53 directly transcriptionally activates PUMA and NOXA to cause cell death (Jeffers et al. 2003; Villunger et al. 2003). The BH3-only proteins directly or indirectly activate BAX/BAK, the executioners of apoptosis, which permeabilize the outer...
mitochondrial membrane and thereby unleash the downstream caspase cascade for cellular demolition (Merino et al. 2009; Llli et al. 2011).

Apoptotic blocks, such as overexpression of prosurvival BCL-2-like proteins (Strasser et al. 1990; Swanson et al. 2004) or loss of proapoptotic BIM or PUMA (Egle et al. 2004; Hemann et al. 2004; Michalak et al. 2009), accelerate c-MYC-driven lymphogenesis. Interestingly, mutations that deregulate the intrinsic apoptotic pathway, including amplifications of the genomic regions encoding MCL-1 and BCL-X (Broukhim et al. 2010), are detected in human tumors and are often associated with poor chemotherapy responses (Khad et al. 2011). Burkitt lymphoma is associated with frequent loss of BIM and/or PUMA expression, in part due to gene hypermethylation [Mestre-Escorihuela et al. 2007; Garrison et al. 2008; Richter-Larrea et al. 2010; Giulino-Roth et al. 2012]. Moreover, many Burkitt lymphomas contain defects in the p53 tumor suppressor pathway, particularly mutations in p53 itself (Farrell et al. 1991; Bhatia et al. 1992) but also overexpression of the ubiquitin ligase HDM2 (called MDM2 in mice) or loss of the p14/ARF locus (Lindstrom et al. 2001).

Although overexpression of prosurvival BCL-2 family members accelerates c-MYC-induced lymphogenesis, it is unclear whether the sustained survival and growth of c-MYC-driven lymphomas depends on the expression of these proteins under endogenous regulation. This remains an important question because knowledge of which prosurvival protein is essential for the sustained growth of a particular cancer will pinpoint the family member that should be targeted by the emerging BH3 mimetic drugs (Lessene et al. 2008). Using innovative gene targeting and drug-mimicking tools, we show for the first time that MCL-1 targeting kills c-MYC-driven mouse and human lymphoma cells even when p53 is mutated. This is remarkable given that we found that p53 does affect the dependency of these lymphoma cells on MCL-1 and suggest that therapeutic targeting of MCL-1 may be a promising strategy for cancer therapy.

Results

Experimental strategy to determine which anti-apoptotic BCL-2 family member is essential for the sustained survival and expansion of MYC-driven lymphomas

To examine the roles of BCL-X\textsubscript{L} and MCL-1 expression under endogenous control in the sustained growth of \textit{E\textsubscript{Mu}-Myc} lymphomas, we generated mice in which we could genetically delete \textit{Mcl-1} or \textit{Bcl-x} at will exclusively within c-MYC-driven lymphoma cells. Specifically, we produced \textit{E\textsubscript{Mu}-Myc} transgenic mice that express a tamoxifen-regulated Cre recombinase-estrogen receptor fusion protein from the ubiquitously expressed Rosa26 locus (Rosa26-CreERT2 mice; Seibler et al. 2003) and bear \textit{llox\textsubscript{P}} targeted [\textit{floxed}, denoted \textit{fl}] alleles of the prosurvival gene \textit{Bcl-x} (Wagner et al. 2000) or \textit{Mcl-1} (Vikstrom et al. 2010) [Supplemental Fig. 1]. As expected, the progeny with all three genetic alterations developed lymphomas with the same latency as standard \textit{E\textsubscript{Mu}-Myc} mice [Supplemental Fig. 2A] because they expressed normal levels of BCL-X\textsubscript{L} or MCL-1. The lymphoma cells were transplanted into C57BL/6-Ly5.1\textsuperscript{+} recipients, which were treated with tamoxifen to activate the Cre-ERT2 recombinase, leading to deletion of Bcl-x\textsubscript{fl} or Mcl-1\textsubscript{fl} alleles exclusively within the malignant cells [Supplemental Fig. 1]. Selected primary lymphomas were infected with an Ub-GFP-Luciferase lentivirus to facilitate monitoring lymphoma progression/regression following Bcl-x or Mcl-1 deletion by imaging for bioluminescence in C57BL/6-albino recipient mice [Supplemental Fig. 1]. In mice transplanted with \textit{E\textsubscript{Mu}-Myc;CreERT2} lymphoma cells lacking any floxed allele [for simplicity, hereafter termed “control”], tumor expansion did not differ significantly between untreated and tamoxifen-treated recipients [\textit{P} = 0.06] [Supplemental Fig. 2B]. This shows that CreERT2 activation per se does not impair the growth of \textit{E\textsubscript{Mu}-Myc} lymphomas.

Homozygous loss of Bcl-x only slightly impairs the sustained growth of \textit{E\textsubscript{Mu}-Myc} lymphomas

Since endogenous BCL-X\textsubscript{H} is necessary for \textit{E\textsubscript{Mu}-Myc}-induced lymphoma development (Kelly et al. 2011), we predicted that it might also be essential for the sustained expansion of such malignant lymphomas. To examine this, primary lymphomas from nine \textit{E\textsubscript{Mu}-Myc;CreERT2,Bcl-x\textsuperscript{fl/fl}} and seven control mice were transplanted into C57BL/6-Ly5.1\textsuperscript{+} recipient mice and cohorts treated with tamoxifen. Homozygous Bcl-x loss resulted in only a modest delay in tumor expansion and slightly prolonged survival of the mice [median survival 25 d for \textit{E\textsubscript{Mu}-Myc;CreERT2,Bcl-x\textsuperscript{fl/fl}} vs. 19 d for the controls; [*] \textit{P} = 0.0367] [Fig. 1A]. Following homozygous Bcl-x deletion, only 4% of the recipient mice [three from 73] showed complete lymphoma regression, which is comparable with the 3% of the tamoxifen-treated mice [one from 32] bearing control tumors.

This result was confirmed by in vivo lymphoma bioluminescence imaging [Fig. 1B]. As early as 7 d after tumor transplant, the recipients displayed a significant lymphoma burden [\textgtrless;=1 \times 10\textsuperscript{7} photon flux per second]. These lymphomas continued to grow following tamoxifen treatment to delete both Bcl-x alleles and overwhelmed the recipients only shortly after the untreated mice had succumbed to the same lymphomas that retained Bcl-x. Efficient deletion of the Bcl-x alleles and loss of the BCL-X\textsubscript{H} protein were confirmed by quantitative RT–PCR [qRT–PCR] and Western blot analyses in paired tamoxifen-treated and untreated lymphomas taken from mice transplanted with \textit{E\textsubscript{Mu}-Myc;CreERT2,Bcl-x\textsuperscript{fl/fl}} lymphomas [Supplemental Fig. 3]. These data reveal that malignant \textit{E\textsubscript{Mu}-Myc} lymphomas can continue to grow without endogenous BCL-X\textsubscript{H} expression.

Loss of Mcl-1 substantially impairs the sustained growth of \textit{E\textsubscript{Mu}-Myc} lymphomas

In parallel experiments, we investigated whether MCL-1 was essential for the sustained growth of \textit{E\textsubscript{Mu}-Myc} lymphomas. Cohorts of C57BL/6-Ly5.1\textsuperscript{+} mice were transplanted with independent primary lymphomas from six
Em-Myc;CreERT2;Mcl-1fl/fl and seven control mice, and their survival was compared following tamoxifen treatment [Fig. 2]. Strikingly, in 30% of the recipients, homozygous deletion of Mcl-1 provoked complete lymphoma regression and extended survival (>180 d post-transplant) [Fig. 2A]. The dramatic tumor regression was confirmed by bioluminescence imaging of lymphomas transplanted into C57BL/6-albino recipient mice [Fig. 2B]. Importantly, even the tamoxifen-treated recipients that relapsed exhibited substantially extended survival compared with those bearing control lymphomas (median survival 35 d for mice bearing Em-Myc;CreERT2;Mcl-1fl/fl lymphomas vs. 19 d for those bearing control lymphomas; [****] P < 0.0001).

Remarkably, even heterozygous Mcl-1fl loss substantially impaired sustained lymphoma growth: 20% of recipient mice bearing Em-Myc;CreERT2;Mcl-1fl/+ lymphomas that relapsed following tamoxifen treatment had escaped deletion of their conditional Mcl-1 alleles mostly because they had undergone selection for loss of CreERT2 expression [Fig. 3A,B]. Western blot analysis of these tamoxifen-treated tumors confirmed that MCL-1 protein expression was not reduced [Fig. 3B]. In addition, the minority of Em-Myc;CreERT2;Mcl-1fl/+ lymphomas that did relapse as huCD4-positive following tamoxifen treatment had only recombined one allele of Mcl-1 and continued to express MCL-1 protein (Fig. 3C,D). By inference, the survival curves described earlier grossly underestimate the role that MCL-1 plays in the sustained growth of Em-Myc lymphomas. Indeed when animals that succumbed to relapsed lymphomas that had selected...
against loss of Mcl-1<sup>fl</sup> alleles were removed from the analysis (and those lymphomas that had mutated p53 alleles were also removed from the survival curves) [Fig. 5A; see below], nearly 100% of animals survived lymphoma-free long-term (>180 d post-transplant) [Fig. 3E]. These findings reveal that even heterozygous Mcl-1 loss is highly detrimental for the sustained in vivo growth of malignant E<sub>M</sub>-Myc lymphomas, indicating that relatively weak targeting of MCL-1 might have therapeutic benefits in MYC-driven cancers.

The sustained growth of human Burkitt lymphoma cells depends on the expression of MCL-1

We sought to translate these findings into the human disease setting. Western blot analysis of Burkitt lymphoma cell lines revealed that all expressed MCL-1 with heterogeneous expression of BCL-X<sub>L</sub> and, as previously reported [Henderson et al. 1991] little to no BCL-2 (Fig. 4A). As a control for the BCL-2 antibody, we showed that the X50-7 and Awa-tr lymphoblastoid cell lines expressed high levels of this prosurvival protein [Fig. 4A], as reported [Henderson et al. 1991].

To examine the impact of targeting BCL-2 prosurvival proteins on Burkitt lymphoma growth, we developed a novel assay based on doxycycline [dox]-inducible expression [from a lentiviral vector] of genetically engineered variants of the BH3-only protein BIM<sub>S</sub> with select binding specificities for distinct BCL-2 prosurvival proteins [Fig. 4B; Chen et al. 2005; Lee et al. 2008]. These polypeptides have a mechanism of action similar to that of BH3 mimetic drugs; i.e., they antagonize BCL-2 prosurvival protein function by engaging a hydrophobic ligand-binding groove on their surface [Lee et al. 2007, 2008; Souers et al. 2013]. The wild-type BIM<sub>S</sub>, which binds with high affinity to all BCL-2 prosurvival proteins, served as a positive control for the integrity of the intrinsic apoptotic pathway. Mutant BIM<sub>S4E</sub>, which does not bind to any BCL-2 prosurvival family member, thus served as a negative control. L62A/F69A mutant BIM<sub>S2A</sub> preferentially binds MCL-1, and BIM<sub>S</sub>BAD binds to BCL-2, BCL-X<sub>L</sub>, and BCL-W. Western blotting verified inducible expression of all BIM<sub>S</sub> variants in Rael-BL (Fig. 4C) and other Burkitt lymphoma cell lines (Supplemental Fig. 4A). All Burkitt lymphoma cell lines tested were highly sensitive to the expression of wild-type BIM<sub>S</sub>, demonstrating that they had an intact intrinsic apoptotic pathway. Conversely, as expected, these cells were not affected by BIM<sub>S4E</sub> (representative FACS plots are shown in Supplemental Fig. 4B).
Figure 3. Most Em-Myc lymphomas that relapse following tamoxifen treatment have escaped Mcl-1 homozygous allele recombination. (A) FACS analysis to detect expression of huCD4 [reporter for Mcl-1 homozygous recombination] on the surface of two representative Em-Myc;CreERT2;Mcl-1+/+ and Em-Myc;CreERT2;Mcl-1fl/fl lymphomas that had relapsed in recipient mice after tamoxifen treatment [transplanted lymphoma cells stained positive for Ly5.2]. Approximately 60% of the relapsed Em-Myc;CreERT2;Mcl-1+/+ and 40% of the relapsed Em-Myc;CreERT2;Mcl-1fl/fl lymphoma cells had escaped Mcl-1 homozygous allele recombination and, as such, were huCD4-negative [like the sample at the left of each pair], whereas ~20% of the relapsed Em-Myc;CreERT2;Mcl-1+/+ and 60% of the relapsed Em-Myc;CreERT2;Mcl-1fl/fl lymphomas had efficiently recombined at least one Mcl-1 allele, as reflected by staining positive for huCD4 [like the sample at the right of each pair]. (B) Immunoblotting to detect MCL-1 and CreERT2 protein expression (probing for Actin was used as a loading control) in extracts from the spleens, lymph nodes, or thymuses of sick mice that had been transplanted with Em-Myc;CreERT2;Mcl-1+/+ or Em-Myc;CreERT2;Mcl-1fl/fl lymphomas. Three independent, paired control, and tamoxifen-treated tumors of each genotype were analyzed (note that one of the Em-Myc;CreERT2;Mcl-1fl/fl tumors [#3] examined never relapsed after tamoxifen treatment). Mcl-1 knockout (KO) mouse embryonic fibroblasts (MEFs) were used as a control to confirm the specificity of the MCL-1 antibody (neg control). (C) DNA PCR analysis of recombined Mcl-1 and unrecombined (intact) floxed alleles in Em-Myc;CreERT2;Mcl-1+/+ mice that had relapsed following tamoxifen treatment. Three independent, paired control, and tamoxifen-treated tumors were analyzed. Mcl-1 knockout [KO] MEFs were used as a control (neg control) to confirm the specificity of the MCL-1 antibody. (D) Survival curves of C57BL/6-Ly5.1+ recipient mice transplanted with Em-Myc;CreERT2;Mcl-1+/+ or Em-Myc;CreERT2;Mcl-1fl/fl lymphomas that had wild-type p53 genes following tamoxifen treatment and excluding those lymphomas that escaped Cre-mediated deletion of one or both Mcl-1 alleles. C57BL/6-Ly5.1+ recipient mice transplanted with Em-Myc;CreERT2; black line] lymphoma cells and treated with tamoxifen are shown for comparison. In total number of recipient mice analyzed, [N] number of independent lymphomas tested. Efficient heterozygous and homozygous deletion of Mcl-1 significantly delayed lymphoma growth. ***P < 0.0001. For the mice transplanted with the control Em-Myc;CreERT2 lymphomas, 3% regressed, and the overall median survival was 19 d. For the mice transplanted with the Em-Myc;CreERT2;Mcl-1+/+ lymphomas, 94% regressed, and the overall median survival was >180 d. For the mice transplanted with the Em-Myc;CreERT2;Mcl-1fl/fl lymphomas, 100% regressed, and the overall median survival was >180 d.
Notably, all Burkitt lymphoma cells were sensitive to BIMS2A, indicating a dependency on MCL-1 (Fig. 4D; Supplemental Fig. 4D). Ramos-BL, BL31, and Sav-BL were also sensitive to BIMSBAD (and, accordingly, also to treatment with ABT-737, which targets BCL-XL, BCL-2, and BCL-W), albeit for Ramos-BL and BL31, significantly less than to BIMS2A, indicating only a partial dependency on BCL-XL (Fig. 4D; Supplemental Fig. 4C,D). Kinetic binding analyses using the Biacore confirmed that the more potent killing activity of BIMS2A versus BIMSBAD on most cell lines reflected the dependence of these cells on MCL-1 rather than a greater capacity of BIMS2A to engage MCL-1 compared with the ability of BIMSBAD to bind BCL-XL. Indeed these Biacore binding assays showed that the affinity of the BAD-BH3 is actually 

20-fold higher for BCL-XL (similar to that of wild-type BIMS BH3) than the affinity of BIMS2A for MCL-1 due to a significantly faster dissociation rate in the MCL-1 interaction.
Kelly et al.

Supplemental Fig. 4E. Collectively, these results show that the sustained survival and growth of Burkitt lymphoma cells is dependent on MCL-1 either alone or with a contribution by BCL-XL.

Mutations in p53 reduce but do not ablate the dependency of c-MYC-driven mouse and human lymphomas on MCL-1

Although most transplanted Eμ-Myc mouse lymphomas (14 from 23 analyzed) could not continue to grow following heterozygous recombination of Mcl-1 fl/fl, a minority of relapsing lymphomas (nine from 23 analyzed) did display heterozygous Mcl-1 fl/fl allele deletion, as demonstrated by huCD4 immunostaining (Fig. 3A). We were interested to understand why these lymphoma cells were less dependent on MCL-1 for their growth, since such insights will be critical for predicting the therapeutic response of c-MYC-driven lymphomas and other cancers to MCL-1 antagonists. Interestingly, we noticed that most lymphomas capable of growth following transplantation and heterozygous Mcl-1 fl/fl loss (seven of nine identified) displayed dramatically increased expression of the tumor suppressor p53 (Figs. 3D, 5A), a hallmark of p53 gene mutations. DNA sequence analysis confirmed the presence of mutations affecting known “hot spot” residues (Freed-Pastor and Prives 2012) within the DNA-binding domain of p53 in the primary lymphomas capable of growth following transplantation and heterozygous deletion of Mcl-1 (Figs. 3D, 5B). This suggests that the presence of existing mutations in the p53 gene decreased the dependency of these tumor cells on MCL-1. An additional relapsed lymphoma of genotype Eμ-Myc; CreERT2;Mcl-1 fl/fl (#6) showed evidence of p53 pathway mutation (increased p19ARF protein expression) upon tamoxifen treatment (increasing the frequency to eight of nine lymphomas showing perturbation of the p53 pathway) (Fig. 3D). As a control, we sequenced the p53 gene in seven of the 14 lymphomas that expressed physiological (i.e., very low/barely detectable in the absence of genotoxic stress) levels of p53 (indicative of wild-type nonmutated p53 genes) and were not capable of growing following heterozygous loss of Mcl-1 and confirmed that their p53 genes were wild type. This highlights a novel and highly specific interplay between malignant cell survival dependency on MCL-1 and the dependency of c-MYC-driven mouse and human cancers.

Discussion

Up to 70% of human cancers display deregulated c-MYC overexpression (Boxer and Dang 2001; Sanchez-Beato et al. 2003). Identifying the cellular factors critical for the growth of c-MYC-driven cancers therefore remains an important objective for designing novel treatment strategies.

We investigated this by using two novel, innovative approaches: conditional deletion of Mcl-1 or Bcl-x genes at will in Eμ-Myc lymphomas within the whole mouse or inducible expression of polypeptides that inhibit specific BCL-2 prosurvival proteins (mimicking the action of drugs that target these proteins, e.g., ABT-737 or ABT-263/navitoclax) in human Burkitt lymphoma cells. We found that although BCL-XL is essential for Eμ-Myc-induced lymphoma development (Kelly et al. 2011), the loss of BCL-XL had only a minimal impact on sustained tumor growth. Consistent with this, treatment of Eμ-Myc lymphomas with the BH3 mimetic ABT-737, which targets BCL-2, BCL-XL, and BCL-W (Oltersdorf et al. 2005; van Delft et al. 2006), does not cause tumor regression (Mason et al. 2008), suggesting that these three prosurvival proteins are dispensable for sustained Eμ-Myc lymphoma growth. In contrast, sustained growth of Eμ-Myc lymphomas was exquisitely dependent on MCL-1. Remarkably, even heterozygous deletion of Mcl-1 was sufficient to result in complete regression of ~20% of tumors, allowing long-term survival of formerly lymphoma-burdened mice. Strikingly, analysis of the lymphomas that did relapse revealed that ~60% had escaped Mcl-1 deletion (mostly due to loss of the Cre recombinase). Indeed, when the animals bearing lymphomas that escaped Mcl-1 fl/fl allele deletion (and had not acquired mutations in p53) were removed from the analysis, nearly 100% survived lymphoma-free long-term (>180 d post-transplant) (Fig. 3E). Importantly, this translated into the human disease setting, where we found that MCL-1 blockade efficiently killed Burkitt lymphoma cells, with a lesser impact of BCL-XL targeting observed in some lines.

An MCL-1 dependency was also detected in AML mouse models and human AML-derived cell lines (Xiang...
Mutations in p53 reduce but do not ablate the dependency of c-MYC-driven mouse and human lymphomas on MCL-1. (A) Immunoblotting to detect stabilized p53 proteins, indicative of a mutant p53 protein, in extracts from 17 $\text{Em-Myc,CreERT2,Mcl-1}^{+/+}$ and six $\text{Em-Myc,CreERT2,Mcl-1}^{+/−}$ lymphomas. All but two of the samples were extracted from transplanted and tamoxifen-treated lymphomas. The two exceptions were $\text{Em-Myc,CreERT2,Mcl-1}^{+/+}$ #9, which was a primary lymphoma, and $\text{Em-Myc,CreERT2,Mcl-1}^{−/−}$ #3, which was a transplanted but not tamoxifen-treated lymphoma (this particular lymphoma has the deletion of two bases that introduces a premature stop codon in the p53 gene). Probing for HSP70 served as a loading control. (B) Summary of the p53 mutations detected in $\text{Em-Myc,CreERT2,Mcl-1}^{+/+}$ and $\text{Em-Myc,CreERT2,Mcl-1}^{−/−}$ lymphomas as detected by DNA sequence analysis. The mutations are listed as wild-type (wt) amino acid (aa) affected, amino acid position, and mutant amino acid. The frequencies at which the mutations were detected in the lymphomas and the human equivalents of the mutations are listed. The sequence alignment for murine p53 was performed using Ensembl transcript number ENSMUST00000108658 as the reference transcript. (C) Immunoblotting to detect the expression of HDM2, p53, and β-Actin (loading control) in human Burkitt lymphoma cell lines. (D) Summary of the p53 pathway aberrations detected in the human Burkitt lymphoma cell lines. The p53 mutations present in each cell line is listed as wild-type [wt] amino acid [aa] affected, amino acid position, and mutant amino acid, and the number of alleles affected is also detailed.
et al. 2010; Glaser et al. 2012]. This finding and the observation that ~10% of diverse tumors contain somatically acquired amplifications of the genomic region harboring MCL-1 [Beroukhim et al. 2010] highlight the importance of developing BH3 mimetic drugs that selectively target MCL-1 for treating human cancers. A concern is that MCL-1 is required for the survival of hematopoietic stem/progenitor cells [Opferman et al. 2005] and several other critical cell types, including cardiomyocytes [Opferman et al. 2003; Vikstrom et al. 2010; Thomas et al. 2013; Wang et al. 2013]. Importantly, our discovery that MYC-driven lymphomas cannot tolerate even heterozygous loss of Mcl-1 [which should mimic 50% drug-mediated inhibition of the protein], whereas its heterozygous loss is well tolerated in normal tissues [Opferman et al. 2003, 2005; Vikstrom et al. 2010], indicates that it should be possible to establish a therapeutic window for MCL-1 inhibitory drugs.

A novel and highly important finding from this study is the observation that mutations in “hot spot” residues in the DNA-binding domain of the p53 gene can reduce but not abrogate the lymphoma cells’ dependency on MCL-1. Consistent with a recent study that found that p53 mutations are the fourth most commonly detected genetic change in a large panel of Burkitt lymphoma biopsies [Love et al. 2012], we found that ~60% of Burkitt lymphoma lines had acquired mutations in the DNA-binding domain of p53 [Petitjean et al. 2007]. Remarkably, all of the remaining Burkitt lymphoma lines examined displayed some other abnormalities in components of the p53 pathway, such as HD2 overexpression or p14/ARF loss. Importantly, MCL-1 antagonism was able to kill Burkitt lymphomas with p53 pathway defects, suggesting that MCL-1 inhibitory drugs could be efficacious in the treatment of c-MYC-driven cancers bearing p53 mutations.

The network of processes that p53 activates to suppress tumorigenesis are still emerging [Brady et al. 2011; Li et al. 2012; Valente et al. 2013]. The observation that mutation and loss of p53 constitute critical steps in c-MYC-driven lymphomagenesis [Vousden and Lane 2007; Michalak et al. 2009] and that they can facilitate the sustained growth of malignant Eμ-Myc lymphomas with reduced MCL-1 expression highlights the connection between the p53 tumor suppressor pathway and the dependency of malignant cells on prosurvival MCL-1.

Our results are consistent with a model [Fig. 6] in which c-MYC-driven lymphomas are highly dependent on MCL-1 for survival. A reduction of MCL-1 expression through either genetic means or, in the future, therapeutics could induce cell death by disturbing the balance between the proapoptotic p53 targets PUMA/NOXA and prosurvival MCL-1. However, when designing therapeutic strategies for such lymphomas, we need to be mindful that mutations in p53 may prevent oncogenic stress-induced up-regulation of PUMA and NOXA and may thereby render lymphoma cells less dependent on MCL-1. Therefore, for such p53 mutated c-MYC-driven lymphomas, it may be beneficial to activate the intrinsic apoptotic pathway more potently than is needed for tumors that carry wild-type p53.

In conclusion, our findings suggest that MCL-1 targeting may be a viable strategy for cancer therapy, particularly in tumors where deregulated c-MYC expression instills an exquisite dependence (much more so than in nontransformed cells) on this prosurvival protein.

**Materials and methods**

**Mice**

Experiments with mice were conducted according to the guidelines of The Walter and Eliza Hall Institute Animal Ethics Committee. Eμ-Myc transgenic [Adams et al. 1985], Bcl-xL0/0 (Wagner et al. 2000), Mcl-10/0 (Vikstrom et al. 2010), Rosa26-CreERT2 (Seibler et al. 2003), and p53−/− [Jacks et al. 1994] gene targeted mice have all been described previously. All mouse strains were on a C57BL/6-Lys.2m genetic background generated on either this background [Mcl-10/0] and Rosa26-CreERT2 using C57BL/6-derived embryonic stem cells, a mixed C57BL/6x129SV background [Bcl-xL0/0] using 129SV-derived embryonic stem cells, or a mixed C57BL/6×SJL background [Eμ-Myc] using microinjection of C57BL/6×SJL-derived oocytes and then backcrossed for 10 to 20 generations with C57BL/6 mice.

Single-cell suspensions of 3 × 10⁶ Eμ-Myc lymphoma cells in PBS were injected into C57BL/6-Lys.5.1+ or C57BL/6-Tyr-22 (referred to as C57BL/6-albino, The Jackson Laboratory) recipient mice by intravenous (i.v.) tail vein injection. Mice were administered by oral gavage with 200 mg/kg tamoxifen (Sigma-Aldrich) in peanut oil/10% ethanol per day [Anastassiadis et al. 2010] for two consecutive days on either days 5 and 6 or days 10 and 11 post-injection of the tumor cells. Transplants in which the matched control untreated mice did not become sick by 28 d post-tumor cell injection were excluded from the analysis.
Statistical analysis

Graphpad Prism software was used for generating Kaplan-Meier plots and performing statistical analysis (using a log-rank test) to compare the survival of mice injected with lymphoma cells of different genotypes. Graphpad Prism was also used to carry out paired two-tailed t-tests on the death induced in the Burkitt lymphoma cells following dox-inducible expression of the BIMs variants. Specifically, the significance of the extent of cell death induced by BIMs2A (to target MCL-1) expression compared with either inducible expression of BIMs4E (negative control) or BIMsBAD (to target BCL-2, BCL-XL, and BCL-W) was calculated for each of the Burkitt lymphoma cell lines.

Cell culture

**Eμ-Myc** mouse lymphoma cells were cultured in high-glucose Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum (FBS) 100 U/mL penicillin, and 100 mg/mL streptomycin [Gibco], 50 μM β-mercaptoethanol [Sigma-Aldrich], 100 μM asparagine [Sigma-Aldrich], 100 U/mL penicillin, and 100 mg/mL streptomycin [Gibco] at 37°C and 10% CO2. OP9 cells were cultured in αMEM [Gibco] supplemented with 20% heat-inactivated FBS, 1 mM glutamine [Gibco], 10 mM Hepes [Gibco], 1 mM sodium pyruvate [Gibco], 50 μM β-mercaptoethanol, 100 U/mL penicillin, and 100 μg/mL streptomycin. Human cell lines were cultured in a humidified incubator at 37°C and 5% CO2. Virus-producing 293T cells were maintained in DMEM supplemented with 10% FBS. Approximately 6 h prior to transfection, 293T cells were cultured in DME glutamax (Gibco) supplemented with 10% FBS and 25 mM Hepes. Rael-BL, Ramos-BL, Sav-BL, and BL-31 human Burkitt lymphoma-derived cell lines were cultured in RPMI 1640 supplemented with 10% FBS and 25 mM Hepes. Mouse lymphoma cells were cultured in high-glucose -Myc supplemented with 10% fetal bovine serum [FBS] 100 U/mL penicillin, and 100 mg/mL streptomycin. A201.1) and Ly5.2 (clone 5.450.15.2 or AL14A7) were used. To verify recombination of the -flanked allele of Mcl-1, cells were stained with antibodies to human CD4 (clone RPA-T4), BCL-x (BD Biosciences), and human MCL-1 (s-19, Santa Cruz Biotechnology); monoclonal antibodies were used to detect mouse p53 (clone IMX25, Novocastra), p19/ARF (clone 5.1), IgD (clone 11-26C), CD4 (clone H129), CD8 (clone YTS.169), Thy1 (clone T3.24.1), Mac1 [M1/70], and GR1 (clone RB6-8C5). To discriminate host-derived [Ly5.1] from donor-derived [Ly5.2] cells, monoclonal antibodies to Ly5.1 (clone A201.1) and Ly5.2 (clone 5.450.15.2 or AL14A7) were used. To verify recombination of the foxlq-flanked allele of Mcl-1, cells were stained with antibodies to human CD4 [clone RPA-T4], since Mcl-1" recombination subjugates a human CD4 reporter cassette to the Mcl-1 promoter/enhancer [Vikstrom et al. 2010]. Antibodies were produced in our laboratory and conjugated to FITC, R-phycoerythrin (R-PE), or allophycocyanin (APC) according to the manufacturers’ instructions. Where required, Burkitt lymphoma cells were sorted for GFP expression using an AriaW cell sorter (Becton Dickinson).

Immunofluorescent staining, flow cytometric analysis, and cell sorting

To immunophenotype Eμ-Myc lymphomas, single-cell suspensions were stained as described [Strasser et al. 1991] with surface marker-specific antibodies and analyzed using an LSR1 machine [Becton Dickinson]. The following fluorochrome-conjugated antibodies were used: CD19 [clone ID3], B220 [RA3-6B2], IgM [clone 5.1], IgD [clone 11-26C], CD4 [clone H129], CD8 [clone YTS.169], Thy1 [clone T3.24.1], Mac1 [M1/70], and GR1 [clone RB6-8C5]. To discriminate host-derived [Ly5.1*] from donor-derived [Ly5.2*] cells, monoclonal antibodies to Ly5.1 [clone A201.1] and Ly5.2 [clone 5.450.15.2 or AL14A7] were used. To verify recombination of the foxlq-flanked allele of Mcl-1, cells were stained with antibodies to human CD4 [clone RPA-T4], since Mcl-1" recombination subjugates a human CD4 reporter cassette to the Mcl-1 promoter/enhancer [Vikstrom et al. 2010]. Antibodies were produced in our laboratory and conjugated to FITC, R-phycoerythrin (R-PE), or allophycocyanin (APC) according to the manufacturers’ instructions. Where required, Burkitt lymphoma cells were sorted for GFP expression using an AriaW cell sorter (Becton Dickinson).

Inducible expression of BIMs variants in human Burkitt lymphoma cells

To induce expression of the BIMs variants, cells were cultured in medium supplemented with 1 μg/mL dox. The viability of the GFP-positive cells was determined by propidium iodide [PI] staining and FACS analysis in an LSR1 machine. The PI-negative/GFP-positive cells were considered as live cells. The cell death following inducible expression of the BIMs variant was expressed relative to the untreated Burkitt lymphoma cells, which were assigned a value of 1. For the analysis of the BIMs variant expression by immunoblotting, the pan-caspase inhibitor qVD-OPh [25 μM, MP Biomedicals] was added to the dox-treated cells for 24 h to inhibit cell killing.

Direct binding assays to determine the binding parameters of BH3 ligands for BCL-Xl and MCL-1

Direct binding assays were performed at room temperature using a Biacore S1 biosensor exactly as described previously [Lee et al. 2007]. The peptides used were BIMs BH3, DMRPEIWIALQQGGEIYAYYARR, BIMs 2A BH3, DMRPEIWIAQERRIGIDEA NAYYARR, and BADs BH3, NLWAAQRYGRELMSDEFDV SFKKG.

Immunoblotting

Total protein extracts were prepared from cells [primary Eμ-Myc lymphomas and Burkitt lymphoma cell lines] by lysis in onyx buffer, NP40 buffer, or urea buffer containing protease inhibitors [Complete protease inhibitor cocktail, Roche]. Protein content was quantified using the Bio-Rad Bradford assay. Total protein extracts (20 μg) were separated on the basis of molecular weight by SDS-PAGE and Western-blotted onto nitrocellulose membranes. The membranes were blocked in 5% skim milk in PBS and 0.1% Tween20 [blocking buffer] before incubation with antibodies. Polyclonal antibodies were used to detect mouse MCL-1 [Rockland Antibodies and Assays], BIM [Enzo Life Sciences], BCL-x [BD Biosciences], and human MCL-1 [s-19, Santa Cruz Biotechnology]; monoclonal antibodies were used to detect mouse p53 [clone IMX25, Novocastra], p19/ARF [clone 5.3.C3.1, Rockland Antibodies and Assays], ERα [to detect the CreERT2 protein] [clone HC-20, Santa Cruz Biotechnology],
Human p53 cDNA sequence analysis

The human p53 gene status was determined by sequencing of cDNA (Lindstrom et al. 2001). Total RNA was extracted from cells using TRIzol reagent [Invitrogen] according to the manufacturer’s instructions. The cDNA was made from total RNA using the Advantage one-step RT–PCR kit according to the manufacturer’s instructions (Clontech). p53 was sequenced from pooled PCR reactions using the following primers: p53F1 (5’-GAAGATCCGGAGGCGCAGT-3’), p53F81 (5’-CTGAGGTGAGCTCTACCACTACC-3’), p53R789 (5’-AACAACTTATTACCACTGGAGTCTTC-3’), and p53R1179 (5’-AGGATTCAGTCTAGTCAAGC-3’).

DNA extraction, PCR, and DNA sequence analysis

DNA was extracted from cells using the Qiagen DNEasy tissue kit (Qiagen) according to the manufacturer's instructions, and the DNA concentration was quantified using the Nanodrop assay. Exons 4, 5–6, 7, 8, and 9, and 10 of the mouse p53 gene were PCR-amplified from 100 ng of DNA using GoTaq green master mix [M712, Promega] and 3.3 μM primers using 32 cycles of 1 min at 94°C, 1 min at 52°C, and 1 min at 72°C followed by a 5-min extension at 72°C. DNA sequence analysis was performed by Micromon Monash. The following primer combinations were used to PCR-amplify and sequence mouse p53: Ex4F (5’-GCTTCTCTCTGATTCATCC-3’ with Ex6R 5’-GGACCATTTGAAGGTCAACAC-3’), Ex5F 5’-TTGGTGTCCCTTTGATCCAC-3’ with Ex6R 5’-AGGCTGAGTCACTGTCTTC-3’, Ex7F (5’-TAGTGAGGGAGAGGAGCTTC-3’) with Ex7R 5’-CAGGAAGGAGAGGAGGAG-3’, Ex8F 5’-CTCTTGCTGGTGCCGTAAC-3’ with Ex9R 5’-CCTGGAACGACTTACTAAC-3’, and Ex10F 5’-AAACCTCTGTAGGAGGCAGG-3’ with Ex10R 5’-AGTACGTTCTGTCAGGTC-3’. The sequence alignment for murine p53 was performed using Ensembl transcript number ENSMUST00000108658 as the reference transcript.

DNA PCR to detect Mcl-1fl, Mcl-1wt, and recombined Mcl-1 alleles

The wild-type, Mcl-1fl, and recombined Mcl-1fl alleles were PCR-amplified from 100 ng of DNA using GoTaq green master mix [M712, Promega] and 0.5 μM primers using 30 cycles of 40 sec at 94°C, 30 sec at 55°C, and 1 min at 72°C followed by a 5-min extension at 72°C. The following primers were used to detect Mcl-1fl and Mcl-1wt alleles: 5’-GCAACATCGCTCGCGAGCC AA-3’ and reverse 5’-GCCGAGTACAGGTCAAGC-3’. The wild-type PCR product was smaller than the floxed PCR product. The following primers were used for PCR amplification of the recombined Mcl-1fl alleles: 5’-GCACACACATGACAGCGGCTTC-3’ with 5’-GAGTCGCCGATATCATTGC-3’.

DNA PCR to detect homozygous deletion of the CDKN2A (INK4A/ARF) locus

The following PCR primers were used: exon 1B, 5’-TTCTCTTGCTGTCAGCAG-3’; R, 5’-TTATCTCTCTCTCTCTCTGCTTG-3’ and exon 2, 5’-TCTGAGTTGTGAAGCTCT-3’; 42F, 5’-GGAAAATGGAAACTGGAAC-3’. A GAPDH exon 8 fragment served as control for integrity of DNA.
