37

38 **Abstract**

39 **Introduction.** Polychlorinated biphenyls (PCBs) are known endocrine disrupters. A

40 potentially causal association of PCBs with vitamin D has been reported. Higher body mass

41 index (BMI) is associated with lower PCB levels whilst the strongest association of PCBs

42 with BMI is in non-obese individuals. Therefore, this study examined the association of

43 PCBs with vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>) and the active 1,25-dihydrovitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>) in a

44 cohort of non-obese women.

45 **Methods.** 58 female participants (age 31.9±4.6 years; BMI 25.7±3.7 kg/m<sup>2</sup>) had seven

46 indicator PCBs [PCB28, PCB52, PCB101, PCB118, PCB138, PCB153 and PCB180]

47 measured using high resolution gas chromatography, with total PCB level calculated.

48 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> levels were determined by isotope-dilution liquid

49 chromatography tandem mass spectrometry.

50 **Results.** In this cohort, vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>) and 1,25(OH)<sub>2</sub>D<sub>3</sub> levels were

51 50.7±25.3nmol/L and 0.05±0.02ng/ml, respectively. Of those, 28 had vitamin D deficiency

52 [25(OH)D<sub>3</sub> level <20ng/ml (<50nmol/l)]. Total PCBs correlated positively with total group

53 25(OH)D<sub>3</sub> (r=0.22, p=0.04) as did PCB118 (r=0.25, p=0.03). Total PCBs did not correlate

54 with total group 1,25(OH)<sub>2</sub>D<sub>3</sub>; however, PCB180 did correlate positively with 1,25(OH)<sub>2</sub>D<sub>3</sub>

55 (r=0.34, p=0.03) as did PCB153 (r=0.33, p<0.03), with PCB 28 correlating negatively (r=-

56 0.29, p<0.04). In the vitamin D deficient subgroup, total PCBs, PCB153 and PCB180

57 positively correlated with 25(OH)D<sub>3</sub> (p<0.05).

58 Multilinear regression analysis indicated all associations could be accounted for by BMI.

59 **Conclusion.** Though certain PCBs associated with 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>, all

60 associations could be accounted for by BMI. This study therefore indicates that the

61 deleterious effects from PCB accumulation are not mediated by effects on 25(OH)D<sub>3</sub> or

62 1,25(OH)<sub>2</sub>D<sub>3</sub>.

63

## 64 **Introduction**

65 Polychlorinated biphenyls (PCBs) are organic pollutants that persist in the environment due  
66 to their resistance to biotransformation and high lipophilicity (1). Dietary consumption is the  
67 main route of exposure in humans (2) and they are classified as endocrine disruptors due to  
68 their observed thyroidogenic, estrogenic and antiandrogenic actions (3). Vitamin D  
69 deficiency is a global health issue associated with a range of negative health outcomes,  
70 including osteoporosis, cancer, cardiovascular disease, autoimmune diseases and increased  
71 mortality (4, 5).

72 Vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>:cholecalciferol) is endogenously produced by UV-B irradiation of 7-  
73 dehydrocholesterol and subsequently hydroxylated to 25(OH)D<sub>3</sub> by multiple 25-hydroxylases  
74 in the liver (6). 25(OH)D<sub>3</sub> is converted to its active metabolite, 1,25-dihydroxyvitamin D<sub>3</sub>  
75 (1,25(OH)<sub>2</sub>D<sub>3</sub>) primarily in the kidneys by 1-alpha hydroxylase. Greenland sledgedogs fed a  
76 high PCB diet from minke whale blubber showed altered vitamin D levels suggesting a  
77 causal effect of PCB on vitamin D levels (7). Though PCBs showed little association with  
78 vitamin D in pilot whales (8), decreased levels of active 1,25(OH)<sub>2</sub>D<sub>3</sub> were found in rats after  
79 exposure to PCBs (9). In pregnant women, there was a negative trend of PCB association  
80 with 25(OH)D<sub>3</sub> (10). Higher body mass index (BMI) is associated with lower PCB levels  
81 (11), with the strongest associations with BMI being in normal weight/ non-obese  
82 individuals. Therefore, this study was undertaken to look at the association of PCBs with  
83 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> in a group of non-obese women prior to them undergoing *in*  
84 *vitro* fertilization (IVF).

85

## 86 **Methods**

87 *Patient recruitment.* Participants were sequentially recruited without knowledge of their  
88 vitamin D status from the Hull IVF Unit, UK, following ethical approval from The Yorkshire

89 and The Humber NRES ethical committee, UK (approval number 02/03/043). All gave  
90 written informed consent. Prior to IVF, 58 non-obese Caucasian women underwent  
91 venesection; fasting blood samples were taken at Day 21 during the luteal phase of the  
92 menstrual cycle prior to commencement of IVF treatment. Study participants had no other  
93 condition or illness and were required to be medication-free for nine months preceding study  
94 enrollment.

95

96 *Polychlorinated biphenyl measurement.* Samples were analyzed for 7 indicator PCBs  
97 [PCB28, PCB52, PCB101, PCB118 (a dioxin-like PCB), PCB138, PCB153 and PCB180], as  
98 previously described (12). Briefly, PCBs were determined using high resolution gas  
99 chromatography (Thermofisher TRACE 1300) coupled with high resolution mass  
100 spectrometry (HRGC/HRMS, Thermofisher DFS) with quality assurance checks using  
101 previously described methods (13). A sum PCB ( $\sum$ PCB) variable was calculated by adding  
102 the molar concentrations of the PCB congeners analyzed.

103

#### 104 *Vitamin D3 and biochemical parameters*

105 Biochemical and hormonal parameters were measured as previously detailed (12). Isotope-  
106 dilution liquid chromatography tandem mass spectrometry (LC-MS/MS) was used to  
107 determine vitamin D levels (14) with a 25(OH)D<sub>3</sub> cut off of 20ng/ml (50nmol/l) to define  
108 vitamin D deficiency. In brief, vitamin D metabolites (1,25(OH)<sub>2</sub>D<sub>3</sub> and 25(OH)D<sub>3</sub> labeled  
109 internal standards (d<sub>6</sub>-25(OH)D<sub>3</sub> and d<sub>6</sub>-1,25(OH)<sub>2</sub>D<sub>3</sub>) were simultaneously extracted from  
110 250  $\mu$ L serum using supportive liquid-liquid extraction and Diels-Alder derivatization prior  
111 to LC-MS/MS analysis. Chromatographic separations were achieved using Hypersil Gold  
112 C18 column (150x2.1mm; 1.9 $\mu$ ) at flow rate 0.2 ml/min, operated in Electrospray Ionisation

113 (ESI) positive mode and analysed by multiple reaction monitoring (MRM) method. The limit  
114 of quantification (LOQ) for 1,25(OH)<sub>2</sub>D<sub>3</sub> was 10 pg/mL and 25(OH)D<sub>3</sub> was 0.5ng/mL.

115

116 *Statistics.* No previous studies were available to perform a power analysis, therefore this pilot  
117 study was designed according to Birkett and Day (15). Statistical analysis was carried out  
118 using Prism version 9.5.0 (Graphpad, San Diego, USA).

119

## 120 **Results**

121 *Whole cohort analysis.* Demographic and biochemical data for this cohort are shown in Table

122 1. The participants had a mean age of 31.9±4.6 years and a mean BMI of 25.7±3.7 kg/m<sup>2</sup>.

123 Thyroid function and C-reactive protein, as a measure of underlying inflammation, were  
124 normal. Mean levels of vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>) and 1,25(OH)<sub>2</sub>D<sub>3</sub> were 50.7±25.3 nmol/L and  
125 0.05±0.02 ng/ml, respectively.

126 Of the 58 women recruited, 28 had a 25(OH)D<sub>3</sub> level less than 20ng/ml (50nmol/). Levels of  
127 PCBs, 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> are shown in Table 1. PCB28, PCB52 and PCB101 had  
128 detection frequencies of 26%, 7% and 45%, respectively whilst PCB118, PCB138, PCB153  
129 and PCB180 had 100% detection frequency.

130 *Whole group correlations.* Total PCBs correlated positively with total group 25(OH)D<sub>3</sub>  
131 (r=0.22, p=0.04) as did PCB118 (r=0.25, p=0.03) (Figure 1 A, B) though no correlation was  
132 seen for PCB101, PCB52, PCB153, PCB28, PCB180 or PCB138.

133 Total PCBs did not correlate with total group 1,25(OH)<sub>2</sub>D<sub>3</sub> (p=ns) (Figure 1C). However,  
134 PCB180 did correlate positively with total group 1,25(OH)<sub>2</sub>D<sub>3</sub> (r=0.34, p=0.03) as did  
135 PCB153 (r=0.33, p<0.03), with PCB 28 correlating negatively (r= -0.29, p<0.04) (Figure 1  
136 D-F); there was no correlation for PCB101, PCB138, PCB118 and PCB52.

137

138 *Subset analysis of women with and without vitamin D3 deficiency.* When the subset of  
139 women who were 25(OH)D<sub>3</sub> deficient (<20ng/ml) was analyzed, total PCBs, PCB153 and  
140 PCB180 positively correlated with 25(OH)D<sub>3</sub> (p<0.05) (Figure 1 G-I); there were no  
141 correlations with 1,25(OH)<sub>2</sub>D<sub>3</sub> in this subset (p>0.05).

142 *Subset correlations.* When the subset of women who were 25(OH)D<sub>3</sub> sufficient (>20ng/ml)  
143 was analyzed, neither total or individual PCBs correlated with 25(OH)D<sub>3</sub> or 1,25(OH)<sub>2</sub>D<sub>3</sub>  
144 (p>0.05).

145

146 *Correlations with body mass index.* Total PCBs and whole group 25(OH)D<sub>3</sub> and  
147 1,25(OH)<sub>2</sub>D<sub>3</sub> were not associated with BMI (p>0.05). When BMI was accounted for by  
148 multiple linear regression, then those significant associations between total PCBs and  
149 PCB118 with whole group 25(OH)D<sub>3</sub>, and between total PCBs, PCB28, PCB153 and  
150 PCB180 with whole group 1,25(OH)<sub>2</sub>D<sub>3</sub>, became non-significant (p>0.05). When BMI was  
151 adjusted for in the 25(OH)D<sub>3</sub> deficient group, then total PCB, PCB153 and PCB118 no longer  
152 significantly correlated with 25(OH)D<sub>3</sub>.

153

## 154 **Discussion**

155 These data show that certain PCBs were apparently associated with both 25(OH)D<sub>3</sub> and its  
156 active metabolite 1,25(OH)<sub>2</sub>D<sub>3</sub>, in accord with the sledgedog study (7), without adjusting for  
157 BMI. Higher BMIs are reported to be associated with lower serum PCB levels due to  
158 sequestering in liquid rich adipose tissue (11), and with lower 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>  
159 levels (16, 17). In addition, obesity is reported to exacerbate vitamin D deficiency through  
160 decreased bioavailability due to deposition of vitamin D in the body fat compartments (18).  
161 In this cohort of non-obese women, PCB levels did not correlate with BMI, in contrast to a  
162 US population (11), nor did 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>. However, when BMI was accounted

163 for in regression analysis, PCBs were not related to whole group 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>  
164 levels, or with 25(OH)D<sub>3</sub> deficient subjects. BMI is reported to modify associations between  
165 dietary intake and serum PCB levels (11) and in this study was shown to alter the association  
166 between PCBs and vitamin D levels. This further highlights the confounding effects of BMI  
167 in epidemiological studies and the need for such study populations to be BMI matched, as is  
168 the case in this study. The lack of association between BMI and 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>  
169 levels is not surprising given that none of the subjects in this cohort were obese. The lack of  
170 association between PCBs and 25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub> levels when BMI was considered  
171 is consistent with the whale data (8). If there were to be an association between vitamin D  
172 and the PCBs, it would have likely manifest with the highly chlorinated congeners that reflect  
173 long term contamination (PCB118, PCB138, PCB153 and PCB180), rather than with PCB28,  
174 a low chlorinated volatile PCB that is degraded relatively fast and thus reflects acute  
175 contamination (19). The reported negative trend for PCB to be associated with vitamin D  
176 (25(OH)D<sub>3</sub>) in pregnancy may have been confounded by weight change (10) and the  
177 decreased levels of 25(OH)D<sub>3</sub> reported in rats may have reflected the dosage of PCBs given  
178 (9).

179 A multitude of factors affect vitamin D levels in humans. These factors include lifestyle,  
180 smoking, alcohol consumption, exercise, diet, sun exposure, season, atmospheric  
181 components, clothing, sunscreen use and skin pigmentation, as well as age, obesity and the  
182 incidence of several chronic illnesses as has been highlighted in a recent report in Brazilian  
183 women (20). Whilst it was not possible to control for all these factors in the women included  
184 in this study, we did seek to mitigate as many confounders as possible. The women included  
185 were of similar age and BMI; all were Caucasian living in the same geographical area of the  
186 United Kingdom and all were non-smokers. As all of these women were to undergo IVF, then  
187 they all had to stop all alcohol 3 months prior to this study. To circumvent the well-

188 recognized seasonal fluctuations in vitamin D metabolite levels, vitamin D sampling was  
189 performed in this study during the period between March to September, to ensure that  
190 vitamin D targets would be achieved with just 9 minutes of sunlight exposure daily in  
191 Northern England (21). Vitamin D supplement consumption was an exclusion criterion of  
192 the study.

193 Strengths of this study include the state-of-the-art measurement of the PCBs and vitamin D  
194 (25(OH)D<sub>3</sub> and 1,25(OH)<sub>2</sub>D<sub>3</sub>). Limitations include the small numbers of subjects. That all  
195 subjects were Caucasian females could be considered a limitation, as these findings may  
196 therefore not be generalizable to male subjects or those of differing ethnicities, but in this  
197 case it is also a strength as it avoids the confounding effect of ethnicity as noted above.

198 In conclusion, our findings show that PCB levels were not associated with 25(OH)D<sub>3</sub> levels  
199 once BMI was accounted for, indicating that the deleterious effects from PCB accumulation  
200 are not mediated by effects on 25(OH)D<sub>3</sub> or its active metabolite 1,25(OH)<sub>2</sub>D<sub>3</sub>.

## 203 DECLARATIONS

204 *Ethics approval and consent to participate:* All procedures performed in studies involving  
205 human participants were in accordance with the ethical standards of The Yorkshire and The  
206 Humber NRES ethical committee, UK (approval number 02/03/043) and with the 1964  
207 Helsinki declaration and its later amendments or comparable ethical standards.

208 *Consent for publication:* All authors gave their consent for publication.

209 *Availability of data and materials:* All the data for this study will be made available upon  
210 reasonable request to the corresponding author.

211 *Competing interests:* No authors have any conflict of interest or competing interests to declare.

212 *Funding:* No funding was received to perform this study.

213 *Authors' contributions:*

214 AEB analyzed the data and wrote the manuscript. TS supervised clinical studies and edited the  
215 manuscript. DSD performed the polychlorinated biphenyl analyses. SLA and EB contributed  
216 to study design, data interpretation and the writing of the manuscript. All authors reviewed and  
217 approved the final version of the manuscript. Alexandra E Butler is the guarantor of this work.

218 *Acknowledgments:* not applicable

290 **Table 1.** Demographics of the 58 female subjects in the population studied.  
 291

	Female subjects (n=58)	
	Mean	SD
Age (years)	31.9	4.6
BMI (kg/m <sup>2</sup> )	25.7	3.7
CRP (mg/L)	2.6	2.5
TSH (mU/L)	2.4	2.2
Free-T3 (pmol/L)	4.8	0.7
Free-T4 (pmol/L)	11.3	1.8
25(OH)D <sub>3</sub> (nmol/l)	50.7	25.3
1,25(OH) <sub>2</sub> D <sub>3</sub> (ng/ml)	0.05	0.02
PCB28 (ng/g Lipid)	2.6	2.2
PCB52 (ng/g Lipid)	6.7	11.1
PCB101 (ng/g Lipid)	2.7	0.6
PCB118 (ng/g Lipid)	5.6	2.1
PCB138 (ng/g Lipid)	12.0	5.7
PCB153 (ng/g Lipid)	15.7	8.4
PCB180 (ng/g Lipid)	13.5	6.3
∑PCBs (ng/g Lipid)	49.2	21.3

292  
 293 *BMI: Body mass index; CRP: C reactive protein; Free-T3: Free Triiodothyronine; Free-T4: Free Thyroxine;*  
 294 *PCB: Polychlorinated biphenyl*

295 **Figure 1.** Correlations of PCBs with vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>) and 1,25(OH)<sub>2</sub>D<sub>3</sub>. Correlations of total PCBs (A) and PCB118 (B) with vitamin  
 296 D<sub>3</sub> (25(OH)D<sub>3</sub>). Correlations of total PCBs (C), PCB153 (D), PCB180 (E) and PCB28 (F) with 1,25(OH)<sub>2</sub>D<sub>3</sub>. Correlations in the subset of  
 297 women who were vitamin D<sub>3</sub> (25(OH)D<sub>3</sub>) deficient with total PCBs (G), PCB153 (H) and PCB180 (I).
